SHED BY THE PROPRIETORS, THE LANCET LIMITED, NO. 423, STRAND, AND NO. 1, BEDFORD STREET,
IN THE COUNTY OF LONDON, AND PRINTED BY HAZELL, WATSON & VINEY, LD., 52, LONG ACRE, W.C.2.

MCMXXVIII.

INDEX TO VOLUME II., 1928.

REFERENCES AND ABBREVIATIONS

Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, (R. and A.R.) = Reports and Analytical Records, (A.D.) = Clinical Interpretation of Aids to Diagnosis, and (N.P.) = New Preparations.

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

Abdomen, Early Diagnosis of the Acute (Zachary Cope), 5th ed. (R.), 505; Practical Surgery of the (George H. Jnilly) (R.), 1030
Abdominal pain in pregnancy (C. S. Lane-Roberts), 1285; tuberculosis, case of, with extreme emaciation (T. C. Hunter), 752; wall, the slack (J. K. McConnel), 363

Chadwick Lectures

ON THE

HISTORY OF EPIDEMIOLOGY

DURING THE LAST HUNDRED YEARS.*

BY SIR WILLIAM HEATON HAMER,
M.D. CAMB., F.R.C.P. LOND.

LECTURE II.

THE sage, Koheleth, "the Preacher," who lived more than 2000 years ago, said there was "no new thing under the sun." The thought is that of the "Persistence in Change" (Dauer im Wechsel) of Goethe, who elsewhere says "Everything that is wise has been thought already; we can only try to think it once more."

Some have surmised that Koheleth was a physician, and certain passages in the book of Ecclesiastes support this view, and have been said to foreshadow the first Aphorism of Hippocrates, or even Sydenham's doctrine that "Epidemics succeed each other regularly and in series forming as it were a circle." A verse much commented upon runs: "He hath made every thing beautiful in his time: also he hath set the world in their heart, so that no man can find out the work that God maketh from the beginning to the end." It is said that the word translated "world" should be rendered "eternity" (or "history"), and such renderings prompt the suggestion that Koheleth was a bit of an epidemiologist: he would then have realised the limitations of his own "little patch of immediacy," and have proceeded as Prof. Whitehead says we must do, to apply the experience gleaned from that patch to the teaching of bygone times.

Be this as it may, the history of epidemiology is replete with illustrations of such lines of thought.

Thus it has been suggested that one of the most characteristic marks of pandemic influenza is that it is generally acclaimed by mankind as a "new disease," and then, as Dr. Goodall says, and there is no greater living authority on such a point, "there is no such thing as a new infectious disease." The occurrences of 1915–25 almost seem to justify the application to influenza of Alphonse Karr's phrase, "Plus ça change, plus c'est la même chose," and to support Hirsch's somewhat paradoxical declaration that "Influenza, beyond all other acute infective diseases, has manifested at all times and in all places the stamp of uniformity in the aggregate of symptoms." Dr. Charles Creighton's History prompts similar lines of inquiry. The accounts of the "Sweating Sickness," of "Gaol Fevers, Influenzas and other Fevers of the Tudor Period," the great chapters on "Typhus and other Continued Fevers" and "Fevers and Dysentery in Ireland," leading up to "Influenza and Epidemic Agues," in which we are told "Epidemic Agues are joined in the same Chapter with Influenzas for the reason that they can hardly be separated from them in the earlier part of the history," this stirring argument was set out by an historian steeped in the medical learning of the earlier centuries, familiar with the life-work of Sydenham, Willis, and their contemporaries, and with that of the school founded by them, and was critically and appreciatively expounded in relation with the "influenzas," which had appeared under that name, upon the stage of history during subsequent years. Creighton's facts and speculations stirred the minds of his readers between 1894 and 1915, and made them more apt to receive the impressions hammered upon them during the then succeeding years.

Already in the early 'nineties Franklin Parsons laid stress upon the types (pulmonary, cerebro-spinal, and gastro-intestinal) of influenzal prevalences. Moreover, Leichtenstern urged then that "Influenza presents at least two phases, one pandemic and the other endemic, and they follow different epidemiologic rules"; he further expressed two beliefs—first, that "trailing epidemics show diminished morbidity, less wide geographical distribution, scarcely recognisable communicability, slow development and extension, and continuous diminution in frequency and intensity"; and, second, that "in the later epidemics the *vis morbi* became more pronounced with the decrease of the *vis contagii*, owing perhaps to weakened influenza germs entering into closer symbiosis with other pathogenic organisms."

Again, Dr. Goodhart declared in the middle of the 'nineties "influenza is still with us," and it was becoming recognised that in family attacks of influenza the disease was apt to be quite differently manifested in the several sufferers, and, if this was accepted as regarded households, why, it was being asked, was it not credible as regards communities also?

In East Herts, in 1904–5, Dunn and Gordon described their "obscure disease simulating influenza"; then came the cerebro-spinal fevers of Glasgow and Belfast, the poliomyelitis reported upon by Broström in Sweden and by Farrar and Reece in this country, and that of New York in 1916. In London Shirley Murphy more than 20 years ago secured the notification of cerebro-spinal fever and soon afterwards of poliomyelitis and polio-encephalitis, and borough medical officers made careful study of each case notified. As early as Jan. 27th, 1912, it was possible to assure Dr. Reece that cerebro-spinal fever and poliomyelitis were distinguishable, one from the other, by reason of the fact that the record of the former appeared on blue forms and that of the latter on white forms. In the London Annual Reports for 1914–17 account of the behaviour of these two epidemic diseases was given, and in 1915 study of the close relationship between cerebro-spinal fever and influenza in London was made.

Then came the prevalences of 1918, and early in that year it was apparent that "The events of the last few months once more strikingly illustrate the 'posting character,' the unexpected manifestations and the protean behaviour of 'influenza'; and, incidentally, the close connexion between polio-encephalitis (i.e., what has since been called encephalitis lethargica), poliomyelitis and cerebro-spinal meningitis, and influenza, seems to be established." (Annual Report for 1917, p. 2.)

In the Ministry of Health Report of 1920 Sir George Newman gave (p. 16) an account of "our growing experience of the setting of an influenza epidemic"; and the same report sets out in detail the experiences of John Huxham between 1728 and 1752, and presents a summary record (p. 17 and onwards) of similar phenomena collected by various observers, from Sydenham's time down to 1847.

Study of the epidemiological record, then, makes it clear that, so far as the influenzal group of diseases is concerned, the natural history method, the method of Hippocrates, is that which must primarily be relied upon.

Dr. Adams tells us that it is very difficult to assign the cases described in the first book of the Epidemics of Hippocrates to their appropriate disease categories. The reason, he says, is that they are "directly drawn from Nature." Sydenham followed this method, and Dr. Payne not many years ago remarked that it is sometimes impossible to decide as to the nature of the prevalences he is discussing. Nowadays we are very prone to think in terms of "causal organisms" (as we used to call them; they are really many of them just "associated organisms"), whereas Sydenham and his followers unravelled the relationships between *associated prevalences of epidemic diseases*, and we are beginning to realise that it behoves us, too, to think in epidemics as well as in micro-organisms.

The outcome of all this may be best appreciated by focusing attention upon Sydenham's treatment of the difficulties with regard to influenza; but it must be a reversion to Sydenham's matured views, not merely to the tentative and, as would now appear, somewhat prematurely conceived doctrines enunciated in those wonderful opening chapters of his Medical Observations.

This first draft, so to speak, underwent in Sydenham's own mind a considerable amount of revision; the original sketch was, however, incorporated in a revised edition in 1675, and, achieving in this form, as it soon did, a world-wide reputation, has not unnaturally been commonly regarded as representing his final view; examination of the development of the conceptions revealed in the writings of the older Sydenham will, however, show that this was very far from being the case. Already in 1675 (Med. Obs. V., vi. 6) it appears he was beginning to concern himself with what now seems a somewhat meticulous enumeration of differentiæ between the "stationary fevers" of his earlier constitutions, and, even at that date (V., v. 1–3, and V., vi. 1–2) he noted the resemblance of his first stationary fever to the fever of the winter of 1675, to which, and to the successors of which, he makes fuller reference in the letter to Dr. Brady of 1680 (paras. 54–57). He speaks of it as the "depuratory fever," the "standard fever of Nature," the "fever upon which Hippocrates and other great physicians of antiquity have commented."

One never need feel surprise at coming across some new light in studying Sydenham, and it is not to be wondered at, therefore, that a pearl of great price is to be found hidden in what is at first sight a somewhat unpromising Postscript to his "Tractate on Dropsy" written in 1683; here, after two and a half centuries, we can still glimpse one of his flashes of inspiration.

---

* Being two lectures delivered in London under the Chadwick Trust on Feb. 16th and 23rd, 1928. Lecture I. appeared in THE LANCET last week.

It relates to an epidemic following after that intriguing fever of 1675 already alluded to above. He has pondered over this and its successors with special fondness, and now he encounters the prevalence of 1679 which has been hailed by modern epidemiologists as an influenza trailer. This led him formally to abandon the impression he had at first entertained that the fever of 1679 was something new. He says it must be reckoned as a common "intercurrent," and he styles it the "winter fever"; then later still (Sched. Mon., 1, 4) he explains that, while at first disposed to regard this "winter fever" as just an "intercurrent"—i.e., as "a bastard peripneumony which occurs in all winters alike," he now realises that it is entitled to rank as a stationary fever; he proceeds, therefore, to execute a full-length portrait of it (Sched. Mon., 1), and there it stands, an unmistakable example of a cerebro-spinal influenza of the seventeenth century, of which the London cerebro-spinal fever of 1915 was, as was claimed at the Royal Society of Medicine at the time, an indubitable lineal descendant. In the final paragraph of Sydenham's account (loc. cit., 46) he has another inspiration, for he says of this stationary fever, "It may be a spirituous and subtle beginning of something else, the germ perhaps of the depuratory fever now exploded, but which the plague followed." Of course, as we now know, it was the precursor of the influenza of 1688, just as the London cerebro-spinal fever of 1915 was the precursor of the great influenza of 1918.

The new light afforded by demonstration of the relationship of this fever of 1685 to the succeeding influenza, and especially the clear recognition, which has just been noted, by Sydenham of the possibility, nay likelihood, that this 1685 fever was identical with the stationary fever ("depuratory fever") of 1661–64, in which he had been so greatly interested nearly a quarter of a century previously, enable us step by step to trace the development of his maturing view that the standard fever of 1661–64, that of the winter of 1675, the depuratory fever, the "winter fever" of the Postscript of 1683 above referred to, the fever of 1685, and we must now add the influenza of 1688 (though that was the year of Sydenham's death), were all phases of one abiding influence. There is here, in fact, the germ of that modern conception "endemic influenza."

In recent discussions regarding Sydenham's Constitutions at the Royal Society of Medicine, while there has been some difference of opinion on the general questions at issue, there has been practical unanimity concerning the special application of his thesis to epidemic prevalences associated with influenza. It may be of interest, therefore, briefly to indicate the extent to which twentieth century findings concerning the influenzal constitution were adumbrated by Sydenham.

In the first place, Sydenham's account of his fifth constitution, that of part of the year 1673 and of the whole years 1674 and 1675, is now recognisable as the classical description of an influenzal constitution. It comprehends a widespread influenza occurring (to use Sydenham's terminology) in a setting of "comatose fevers." This series of prevalences quite plainly furnishes the almost exact counterpart to the great influenzas of 1918 with their precursors and trailers. Thus, following upon comatose fevers in 1673 and 1674, we are told, the fever of 1675 "spread its ravages far and wide" in July (exactly, it may be noted, in passing, as it did in 1918); the attack was first upon the bowels and then the head, the fever, however, "having the predominance and taking the lead of the other maladies of the year." The notion was entertained by some, says Sydenham, that the complicating "dysentery and diarrhœa which did so much mischief arose from these two diseases; whereas in reality they were to be imputed to the fever" (i.e., to influenza). "Everyone, however, who had any practice among the sick, knew the predominance of the fever and knew also that the aforesaid dysentery and diarrhœa were symptoms rather than essential and primary diseases." (Med. Obs., V., i., 5; see also V., ii., 23.) "This was the course which was held by the fever throughout the autumn, sometimes it attacked the head, sometimes the bowels. It everywhere put on the symptoms of the particular part affected." At the end of October the weather "suddenly changed to wet and cold. This brought on coughs and catarrhs, which" (says Sydenham) "were more numerous than ever I remember them to have been," and upon these "supervened the stationary fever of the year (as in October–November, 1918), and this, having once taken its hold, increased, and varied in some of its symptoms from the fever of the previous part of the year" (attacking, however, now the lungs and pleura instead of the head and bowels). At the end of November the catarrhs and coughs suddenly decreased. "The fever, however, remained as before, just as it was before the catarrhs" (V., i., 7). "All that suffered, suffered first in the head, back, and limbs; these being the symptoms" (of the influenza, as we should say, but keeping Sydenham's wording it reads) "which were most constant to the non-pleuritic fevers, which preceded and which characterised them to their close." (VI., i., 6.)

Sydenham's description is unmatchable for vision, precision, and terseness of expression; moreover, he explicitly reiterates, again and again, that while the bowels, brain, and lungs were successively attacked, the accompanying diarrhœa, stupor, and pneumonia were all merely symptomatic of one stationary fever, and the characteristic marks of that fever he stamps most unmistakably upon it.

In the second place, it is clear that the pulmonary trailer of 1679 riveted Sydenham's attention upon the special type of prevalence with which the influenzas of "the 'nineties" made Western Europe so familiar; after much study and reflection he concluded that the said fever recurring winter after winter was identifiable *not only* with the fever of 1685 (see R.S.M., loc. cit. 1915) and thus heralded in that "spirituous and subtle something" (the influenza of 1688), but was also identifiable with the "depuratory fever," which had accompanied and been found to be interchangeable with the "intermittents" of 1661–64 (i.e., with the gastro-intestinal, pulmonary, and nervous trailing epidemics) following the great influenza of 1658.

Then, thirdly, we have Sydenham's statement (M.O., V., vi., 2) regarding the interchangeability of the intermittents and the stationary fevers, which "ran parallel with them"; and he formulates the thesis (letter to Dr. Brady, para. 56) that in intermittents "Nature works hastily and gets over in less time than is regular the processes by which she first tempers and afterwards discharges the morbific matter." "Depuratory fevers," he adds, "are different; 13 or 14 days elapse before the appearance of any signs of the concoction of the febrile matter, which is then to be ejected by sweats; or rather by a somewhat free transpiration." Again, in para. 57, he contrasts the later "humoral or earthy fevers, which cleared the blood but slowly," with the earlier fevers of the same constitution, "which were subtle in principle, intermittent in type and did their work more rapidly."

Elsewhere[1] the application to the study of the influenza wave of this mutation theory of Sydenham has been discussed; to use modern phrasing, he is contending that the virus of influenza works more easily and rapidly near the crests of the pandemics and with more difficulty and more slowly in the intervening troughs.

Furthermore, there may also be deduced from Sydenham's own writings the conclusion that between the widespread prevalences on the crests of the great pandemic influenza waves and the depuratory fevers (or endemic influenzas) of the troughs, ripples of intermittents appear, both on the ascending and descending slopes of the great ocean rollers. Sydenham, as is well known, identified the intermittents of 1675–79 (following the great influenza of 1675) with those of 1661–64 (following the great influenza of 1658); but he also makes it clear (IV., i., 5 and 6) that similar intermittents preceded both the influenza of 1675 and that of 1688 (Sched. Mon. I., 46).

Let us recall his statement made in 1675 (I., ii., 21–23):

> "I may state at once, that to reduce into classes all the species of epidemics, to arrange them according to their phenomena, to work out their several idiopathic characteristics, to determine in detail the proper method of treatment for each of them is a work so difficult, an arrangement requiring so much leisure and opportunity, a cycle so little coincident with any recognised sequence of years, that the lifetime of no single physician would suffice for the collection of a sufficiency of data." But he was better than his word, for we find him later adding material contributions to what (in 1675) he had described as "My mite, such as it is, towards the foundation of a work, that in my humble judgment shall be beneficial to the human race."

As so much has been said and thought recently concerning influenza, it may be of interest to refer to a question forced into prominence of late years, that of the damage inflicted by that disease upon the nervous system. The relation of cycles of genius to prevalences of influenza was recently undertaken with a view to ascertaining whether "influenza years" were years in which such damage especially resulted. In the first instance the attempt had been made to obtain confirmation of the suspicion that influenza plays a part in the causation of insanity. The records of insanity, however, are of such recent date, and are so beset with fallacies, as to make this task an exceedingly difficult one; it seemed then to be a more practicable plan to begin, as it were, at the other end—i.e., with men of genius, and to try to ascertain whether the extent to which their nervous systems are damaged by influenza can be gauged with any approach to accuracy.

---

[1] Proc. Roy. Soc. Med., 1927, xx., Epidem. Sect., 69–61.

At first sight it was surmised that the influence, if any, might be expected to be most conspicuously revealed at the age of special intellectual development and of main output of mental work, say at 25–50. On further consideration it was decided to examine in like manner a corresponding graph for the earlier age-period 0–25. Later still it seemed desirable that the graph for ages 50–75 should also be constructed. The three graphs present some resemblances and some noteworthy contrasts.

As they relate to the same lives at different age-periods—in youth, in early and in later maturity, respectively—it is obvious that the three contours will show a considerable degree of resemblance. On examining the special effect of groups of "influenzal years" it is at once apparent that they operate prejudicially in all three graphs, but their evil influence is most discernible in the 0–25 graph.

The marked influenza periods of the last three centuries—1657–93, 1708–18, 1729–43, 1757–67, 1780–90, 1798–1807, 1824–37, 1842–51, 1857–64, 1890–95, and 1915–25, were scrutinised seriatim to ascertain the depth of the depression produced at these times in the outlines of the graphs for 0–25, 25–50, and 50–75 years of age respectively. In the case of each depression an *index* was obtained representing the proportion of loss per number of lives at risk for each group of influenzal years. This index was found to vary from practically *nil* in three instances to the *highest limit* of approximately one-half.

The question at once rises whether on the average these indices approximate to what might have been expected a priori in dealing with *any* epidemic disease causing mortality in the population at large and incidentally influencing the output of work by men of genius?

In the first place, no epidemic disease of which precise statistics are available causes such ravages as are shown in these graphs relating to the influenzal group of diseases. Limiting consideration, then, to that group, the greatest recorded rates of mortality for the population as a whole was that of 1918. The total London loss from influenza in that year was about 18,000, rather more than one-fifth of the total deaths registered. So high an "index" as this was not forthcoming in any earlier group of years, though the *proportion of total deaths to population* was equally high in two individual years of special influenza prevalence during the middle third of the eighteenth century. The average index, taken over the whole of the prevalences of the last 250 years, was clearly very much less than one-fifth.

It is hence apparent that the influenzal group of epidemics leave their impress to a quite excessive extent upon men of marked ability as compared with the population as a whole.

It was, in bygone times, almost a commonplace that sweat, influenza, and "volatile typhus" affected "gens aisés," "people of the court," and the "noblesse," in contradistinction to other epidemics which specially attacked the poor, badly housed, and ill-nourished.

One reason for this excessive class incidence may have been that those who used their heads were more liable to suffer than those who used their hands. We must, in fact, be prepared to accept the conclusion that the widespread prevalences of influenza during the last two and a half centuries have levied a specially heavy toll upon men of marked ability; and in some conspicuous instances the facts are on record that the influenzas of past times again and again attacked notable men and women. Chopin, Sterne, Swift, Jane Welsh Carlyle, and William James may be referred to as instances of this, and for the abrupt termination of the lives of many remarkable men (from Shakspere and Cromwell onwards) influenza was presumably responsible.

The critic may urge that, while appreciating that something may be said for approaching the study of epidemiology from the "big endian," as opposed to the "little endian," point of view, he would like to know whether it is likely that anything of *practical* value will result from adopting this method of approach, say, for example, in the case of influenza. Certain conclusions may at any rate be drawn. Influenza is, as Noah Webster said years ago, the "crux of epidemiology." It is not merely, as it was long supposed to be, a "pandemic disease" reappearing once or twice in a generation, but it is ever present, now smouldering and then every 10, 15, or 20 years, bursting into flame. Its great prevalences are especially favoured by war, famine, overcrowding, and free communication with sufferers from the disease in the early stages of their illness. Despite, however, the huge increase of means of intercommunication and traffic during the last 100 years, coupled with entire absence of systematic attempts to limit spread of the disease by sufferers in the early stages of illness, the mortality in London from the influenzal group of diseases appears not to be appreciably greater in proportion to population than it was 150 years ago. The influences that have made for good have been improved feeding, better housing, greater cleanliness, and provision of medical and nursing care in serious cases; but now while continuing to develop resistance on these lines, there *should be added*, thereto, carefully considered measures for preventing sufferers from mixing freely with their fellows in offices, schools, conveyances, and places of assembly, as they do at present while in the early highly infectious stages of illness; above all, it must be appreciated that the most extravagant and bizarre efforts made, under the influence of panic, at times of widespread prevalence, are as nothing compared with steady and continued prosecution of a considered campaign against the influenzal group of diseases, conducted on epidemiological lines.

The conclusion from a survey of the last century of epidemiology would then appear to be that already reached by a number of Chadwick lecturers. It was first stated, however, by Sir William Collins, in a form in which it is particularly applicable to epidemiology in an address on "Physic and Metaphysic," delivered to the Abernethian Society on Feb. 16th, 1905. Sir William, quoting Dr. Martineau, says:—

> "Laplace, in scanning the heavens with his telescope, could find no God, and Lawrence declared that the scalpel in dissecting the brain came upon no soul. Both are unquestionably true, and it is precisely the truth of the second that vitiates the intended inferences from the first. Had the scalpel alighted on some perceptible soul we might have required of the telescope to perform a similar task; and on its bringing in a dumb report have concluded that there was *only mechanism there*. But in spite of the knife's failure, we positively know that conscious thought and will *were* present, yet no more visible yesterday; and so that the telescope misses all but the bodies of the universe and their light avails nothing to prove the absence of a living mind through all. If you have the wrong instrument the objects of your search may well evade you. The test-tube will not detect an insincerity or the microscope analyse a grief."

This question of instruments assumes nowadays very great importance in connexion with epidemic disease, for epidemiologists using field implements sometimes glean very different conclusions from those deduced by bacteriologists employing laboratory implements. As an example "food poisoning" may be referred to. The epidemiological evidence has gradually accumulated during the last three and a half centuries. Dr. J. J. Walsh (International Congress of Medicine, 1913) carries us back to the food poisonings of the Middle Ages, which, he says, were in the main cases of illness (often apparently of infectious illness) with obscure abdominal or cerebro-spinal symptoms; and thus the characters of those supposed "pitiless poisoners," the Borgias, were taken away owing in part presumably to unrecognised prevalences of gastro-intestinal and cerebro-spinal influenza. Ozanam also testifies that epidemic encephalitis was often regarded as due to poisoned food. Crookshank has carefully set out the evidence for acceptance, as cerebro-spinal influenza, of much of the "convulsive ergotism" of past centuries. Even as recently as 1888 we find the

Middlesbrough outbreak of pneumonia ascribed to food. Lichtenstern, however, spoke confidently of "influenza dinners" in the early 'nineties, and Bulstrode's report on the Greenwich outbreak of 1893 was typical of many others in which influenza and not food was presumably at fault.

But the whirligig of time brings in its revenges and many supposed food outbreaks of the 'nineties were studied exclusively from the bacteriological point of view; again, during the recent influenzas, botulism ran riot in the Western States of America and both here and on the continent large numbers of reports on food outbreaks appeared, in which "causal organisms" (complying with appropriate serological tests) were described and exhaustively studied, from many points of view, but not from that of possible association with the prevailing epidemic. In a recent report[2] mention, however, is made of a "considerable number of cases which are ascribed, often very confidently, to food poisoning without any justification." Moreover, we learn that "Medical officers and others have sometimes limited their interest and activity to tracing the outbreak to some given article of food" . . . while "the more distant sources have been left untraced"; even in the report in question, oddly enough, no mention is made of influenza, though the survey relates to outbreaks occurring during years of widespread prevalence of that disease.

The records of these recent years, in fact, abundantly bear witness to the need that field observations and field research should have place as well as laboratory observations and laboratory research, the two sets of findings being placed alongside one another and coördinated together. Given such a consummation, it may be surmised that, in public health, as in other scientific work, an "Age of Professionalism and Specialism" will slowly but surely give place to an age in which interest will be taken in general principles as well as in stubborn and irreducible facts. This is the lesson, which he who runs may read, in the history of epidemiology during the last hundred years.

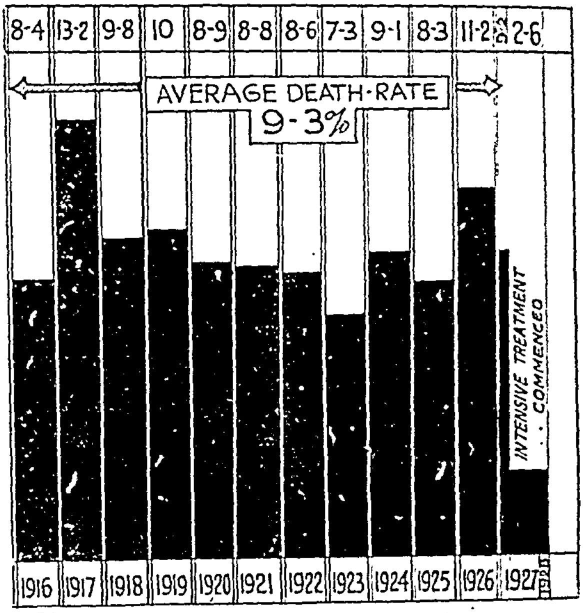
THE INTENSIVE SERUM TREATMENT OF SEVERE DIPHTHERIA.

By H. STANLEY BANKS, M.B. Glasg.,
D.P.H. Camb.,
MEDICAL SUPERINTENDENT, LEICESTER ISOLATION HOSPITAL;
AND
GEORGE McCRACKEN, L.R.C.P. Edin.,
SENIOR RESIDENT MEDICAL OFFICER TO THE HOSPITAL.

This article contains preliminary observations upon the treatment of severe diphtheria by large doses of antitoxin, administered chiefly by the intravenous route. This has been a routine measure for over a year in the City of Leicester Isolation Hospital and, although the period is short, the results justify this report. Perhaps the most striking feature is the reduction in the hospital death-rate from diphtheria. The average death-rate calculated upon all completed cases—i.e., those discharged or died—during the 11 years 1916–26 was 9·3 per cent., the lowest mortality in any year being 7·3 per cent., and the highest 13·2 per cent. The new method was adopted on April 1st, 1927, and during the succeeding period of 12 months—i.e., to March 31st, 1928—the death-rate was 2·6 per cent. Excluding laryngeal cases and patients dying within 12 hours of admission, the death-rate was 1·7 per cent. The chart shows the reduction.

The 300 verified cases dealt with during the period included no less than 27 malignant or severely toxic cases of diphtheria (Group A), most of whom, according to our former experience, would have died under the older method of treatment whereas, under the new conditions, only six died. The very toxic cases amounted to 9 per cent. of the total, and this figure approximately corresponds with the average death-rate for past years. On the other hand, the number of laryngeal cases was exceptionally low during the period, and this fact would tend to keep the death-rate low. Nevertheless, we are convinced that the reduction actually effected in the mortality was chiefly due to the number of severe toxic cases which recovered under the intensive method of antitoxin treatment.

Death-rate (per cent.)—



Years—

Chart showing the percentage mortality of cases of diphtheria treated at the Leicester Isolation Hospital from 1916–28.

Classification of the Cases.

During the year 326 cases were discharged from, or died in, the diphtheria wards, and of these 26 were proved to be not suffering from diphtheria and have been excluded. Of the 300 verified and completed cases, seven were infants with laryngeal diphtheria. The remaining 293 cases have been classified for convenience into three groups, according to the extent of the local manifestations and the degree of toxæmia. Following out the five points of the scheme detailed below and knowing the subsequent history, we have had little difficulty in assigning each case to its appropriate group. The classification cannot always be made with certainty when the case is first admitted, but is generally easy after a few days.

Group A (malignant or severely toxic) comprised 27 cases having the following five outstanding clinical features:—

(1) *Extensive diphtheritic membrane* involving fauces, tonsils, uvula, soft palate, and naso-pharynx. In some the membrane extended over the hard palate even to the teeth and in others covered the nasal mucous membrane. Towards the spreading margin the membrane usually presented a semi-transparent glistening appearance with an ill-defined edge; these characteristics usually signify a rapid spread. Œdema of the fauces adds to the gravity of the case.

(2) *Cervical adenitis and peri-adenitis* of severe degree, the swelling in the neck having the typical rounded contour. The condition varied from the extreme "bull-neck" type with enormous uniform swelling all round the neck to the type which might almost be described as unilateral. In no case was the size of the swelling less than that of a hen's egg.

(3) Nasal discharge generally profuse, sometimes hæmorrhagic, very rarely scanty.

---

[2] Med. Research Rep., 1925, No. 92.

(4) Fœtid odour from the throat, typical of severe diphtheria.

(5) Toxæmia of severe degree characterised, inter alia, by delirium, stupor, and coma in the worst cases, and by great lethargy and hebetude in the others.

Group B (moderately toxic), consisted of 52 cases having the above features, modified as follows:—

(1) Extent of membrane: the tonsils, one of both pillars of fauces, and a small area of soft palate or naso-pharynx covered.

(2) Cervical adenopathy: the cervical glands enlarged to about the size of a walnut and with some degree of peri-adenitis.

(3) Nasal discharge: scanty or absent.

(4) Fœtor from throat: generally nil; sometimes could be detected.

(5) Evidence of toxæmia: the quiet, subdued demeanour of diphtheria, but with mental alertness.

Group C (moderate and mild) comprised the great bulk of the cases (214 in number) and had the following features:—

(1) Extent of membrane: not spreading further than the pillars of the fauces.

(2) Cervical adenopathy: enlarged glands palpable in most cases but not visible.

(3) Nasal discharge: scanty or nil.

(4) Fœtor from throat: generally nil; sometimes could be detected.

(5) Evidence of toxæmia: the quiet, subdued demeanour of diphtheria, but with mental alertness.

Dosage of Antitoxin Employed.

All cases deemed on admission to belong to Group A had antitoxin administered both intravenously and intramuscularly in doses varying from 70,000 to 200,000 units. Generally the dose given on admission was about 50,000 units intravenously and 20,000 intramuscularly. In a few of the worst cases doses up to double these amounts were given on admission. Where there seemed to be an insufficient response in about 12 hours' time a second dose was given. The chief indications for a second dose were: (1) The local condition: the membrane should have begun to become opaque with well-defined raised margins, showing that spread had ceased; the cervical swelling should have become correspondingly reduced. (2) The general condition: the patient should have become appreciably brighter and more alert, showing a diminution of the toxæmia. The latter point is the test par excellence of the adequacy of dosage in the severe toxic cases of diphtheria. If there is no improvement or inconsiderable improvement in the dull stuporous mental condition, then a second large dose of serum intravenously is most certainly indicated. More serum was given 24 and 36 hours after admission if there were insufficient signs of arrest of the disease or of the toxæmia. The average dose of serum actually given in the 27 cases of this group was 71,000 units intravenously and 31,000 units intramuscularly.

In Group B the first dose was generally about 20,000 units intravenously and 8000 to 16,000 intramuscularly. Occasionally a second dose was required. The average dose for the 52 cases of Group B worked out at 19,000 units intravenously and 19,000 units intramuscularly. In Group C no departure was made from the well-recognised dosage for moderate and mild diphtheria—viz., 8000–16,000 units intramuscularly. The average dose in this group worked out at the rather high figure of 14,000 units. This was due, no doubt, to some excess of caution where it was doubtful on admission whether the case should be classified in Group B or Group C.

Technique.

The technique of intravenous injection of large amounts of serum in young children does not, as a rule, present much difficulty after some practice. It takes time, however, and one of more assistants are generally necessary.

The vein of choice is the median basilic at the bend of the elbow, and if failure is encountered here in both arms a superficial vein in front of the ankle-joint or over the dorsum of the foot is explored. In the youngest infants the finest hypodermic needle, and in older children a medium or large bore hypodermic needle is employed. The serum is injected directly from 10 c.cm. or 20 c.cm. Record syringes, preferably with eccentric nozzles. The whole amount to be injected is ready at hand in the syringes before the puncture is made. A tourniquet is applied to the upper arm, and one assistant keeps the arm firmly hyperextended by pressing on the triceps area with one hand and on the anterior aspect of the wrist with the other. When the puncture is made it is essential to withdraw a little blood into the syringe before attempting the injection, since otherwise the needle-point may not be lying actually within the vein. The serum is necessarily injected slowly through such a fine needle, and care must be taken to avoid the entry of air-bubbles into the vein. In detaching the syringe from the needle great care is required to avoid dislodging the needle-point from the vein. The second syringe, full of serum, is attached to the needle as soon as a drop of blood appears at the needle-mount. When the requisite amount of serum has been injected the syringe is detached and the needles left in the vein, and our present practice is then to inject 4 to 8 minims of adrenalin intravenously by attaching a hypodermic syringe. Alternatively ½ c.cm. of pituitrin may be injected intramuscularly. The time taken in the whole process of intravenous injection may be as long as 20 minutes in young or fractious children. Very few children offer resistance, since the injection is painless. Indeed, all children prefer intravenous to intramuscular or subcutaneous injection.

The concentration of serum which we have found suitable is about 1400 units per c.cm., but the viscosity, rather than the concentration, is the important point. Serum of higher concentration is exceedingly difficult to push through the bore of a fine hypodermic needle, while a lower concentration involves the injection of a greater amount of foreign protein.

Immediately after the injection the child is covered with warm blankets and packed round with hot-water bottles, and the foot of the bed is raised. In other words, he is treated prophylactically for the rigor and collapse which has occurred in half our patients within half to three hours. The prophylactic administration of intravenous adrenalin, or of intramuscular pituitrin, promises to reduce the incidence and severity of these reactions.

The rationale of intravenous injection of serum is obvious since the maximum concentration of antitoxin in the blood occurs immediately, whereas after intramuscular injection it occurs in 24 hours, and after subcutaneous injection the maximum concentration is not present for three days.[1] Six hours after an intravenous injection of serum there is ten times more antitoxin in the blood than after subcutaneous injection of the same amount, and 24 hours after intravenous injection there is twice as much in the blood as would have entered it by the subcutaneous route.[2] For these reasons, in toxic cases, the major part of the serum required is injected intravenously for immediate effect, and a relatively smaller amount is given intramuscularly at the same time. The position must be reviewed after 12 hours, and further doses given if required.

This method of treatment differs from standard teaching only in the total amount of serum given. Park's view (1921), based on laboratory and statistical evidence, is that "amounts of antitoxin beyond 25,000 units in a child and 50,000 in an adult, are absolutely unnecessary and useless, and that an initial dose of 10,000 units in a child and 20,000 units in an adult is probably sufficient for the whole course of the disease."[3] Goodall states (1928) that in his experience any amount of serum over 30,000 units, even when spread over two or three days, is wasted.[4] Our practical experience of the past year is in direct opposition to these views. Since we commenced this work we have learned with great interest that V. Bie, of Copenhagen, working on similar lines, has been using doses up to 200,000 or even 300,000 units since 1920. We are indebted to him for sending us particulars of his results for the year 1927, from which it appears that in a series of 1456 cases admitted to his hospital the death-rate was 1·3 per cent. These figures exclude laryngeal cases and patients dying within 24 hours of admission. He divides his cases into eight groups, giving the mortality in each group, and states (in a personal communication) that the death-rate in each group and the total death-rate have remained practically unaltered since he began to use the large doses.

Reactions following Intravenous Serum.

In Group A 11 cases out of 27, and in Group B 19 cases out of 37, receiving intravenous serum had an allergic reaction within half to three hours of the injection. The reaction is generally alarming and includes rigor, pallor, prostration, weak pulse, cyanosis about the lips, anxious staring expression, and pyrexia from 104° to 107° F. It lasts, as a rule, only a few minutes, and is followed by sweating and gradual return to the status quo. It is now treated prophylactically. If necessary, adrenalin, up to 2 c.cm. intramuscularly or 1 c.cm. intravenously, may be injected during the attack. Generally 1 c.cm. intramuscularly is sufficient. We have had no fatality from this reaction, nor has Bie in eight years' experience, but he nearly lost one adult, and considered that he saved the patient by injecting 1 c.cm. of adrenalin intravenously after 2 c.cm. intramuscularly had failed to relieve the condition. On account of this experience, Bie does not now give more than 50,000 units intravenously at a time—i.e., 50 c.cm. of the serum which he uses. We have, however, given as much as 140,000 units intravenously in a single dose, with no reaction whatever, while in another case a dose of 8000 units intravenously was followed by a rigor. The reaction seems to bear a lesser relationship to the size of the dose than to individual idiosyncrasy.

Serum rashes were very common in the first or second week but gave no cause for anxiety.

7. Hæmorrhagic diphtheria: died 1¼ hours after admission.
8. Early cardiac failure: 3 hours after admission (membrane extending to bronchi). Laryngeal case.

Complications of Diphtheria in this Series.

The intensive method of serum treatment reduces not only mortality but also complications, especially the more serious forms of paralysis. In Group A (27 cases) the six who died had, as would be expected, severe paralysis of the heart. Of the remaining 21 cases only eight showed signs of the slighter forms of myocarditis, including extrasystoles and partial heart-block, and only ten had palatal paresis, while ciliary paresis and paresis of limbs were still rarer. Cardiac vomiting and paralysis of swallowing are now extreme rarities in these wards. Considering the extremely severe toxic condition of the cases in Group A on admission, this record is very favourable. In Group B, comprising 52 cases, 37 had intravenous serum and 15 had intramuscular serum only. Of the former seven had slight cardiac palsy (from which all recovered) and one had palatal paresis. In the 15 intramuscular cases there were six cardiac and three palatal pareses, a considerably higher incidence of paralysis than in the intravenous cases. The relative infrequency of severe paralysis greatly lightened the nursing in the convalescent stage. The difference in the actual work of the wards is quite marked. All the anxiety occurs in the acute stage or within the first two days, and after that things go smoothly.

Another way of estimating the effect of the treatment is to consider the average duration of residence in the hospital of recovered cases in Group A. This amounted to 70 days. All who are familiar with the painfully slow recovery of the survivors of the Group A type of patient under the older method of treatment know that it often involves four to six months' residence in hospital.

One of the most remarkable features of our diphtheria wards during the past year has been the rapidity with which almost every patient regained brightness of demeanour and outlook. Finally, in only one of the cases treated by large doses of serum intravenously did the carrier state occur. In this case only out of 64 cases receiving intravenous serum was departure delayed from hospital owing to persistent positive swabs. This, however, may be mere coincidence.

Objections to the Intensive Method.

Three main objections may be urged against the intensive serum treatment of diphtheria. These are: (1) expense; (2) additional work, particularly to the medical staff; and (3) danger from allergic reaction. It must be admitted that the annual increase in serum costs has been about £300 in the Leicester Isolation Hospital. Against this must be placed the saving in life, represented by a reduction of mortality from 9·3 per cent. to 2·6 per cent., and also the saving effected by the curtailment of the period of hospital treatment and lessened nursing costs. This in itself is probably sufficient to balance the additional cost of the serum. Toxic diphtheria should be regarded as an acute emergency, like a gangrenous appendix or a perforated gastric ulcer. It requires immediate expert medical attention and generally takes up half an hour of the doctor's time. It cannot properly be left to nurses, or even to medical men who merely give a haphazard subcutaneous injection of serum, which is equivalent to postponing operation on a gangrenous appendix for three days. The danger from the allergic reaction can be fairly met by prophylactic treatment and the use of adrenalin or pituitrin.

PAYING PATIENTS AT NEWCASTLE-ON-TYNE.—The annual report of Newcastle-on-Tyne Throat, Nose and Ear Hospital records that 12 months ago, owing to lack of support, some of the beds had to be closed. Rather than keep the beds unoccupied it was decided to use them for paying patients, and as a result they have been fully occupied.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—At the annual meeting of this hospital the Earl of Chesterfield, the President, stated that the work was being carried on under makeshift conditions, in a private dwelling which had been adapted and had long been outgrown. There are only 33 beds, whereas at least 50 are needed, together with accommodation for private patients and young children, and space for using the latest scientific methods. In 1927 the 220 in-patients stayed on an average 41 days. The hospital owns in the Uxbridge-road abundant freehold ground for building, but lacks means.

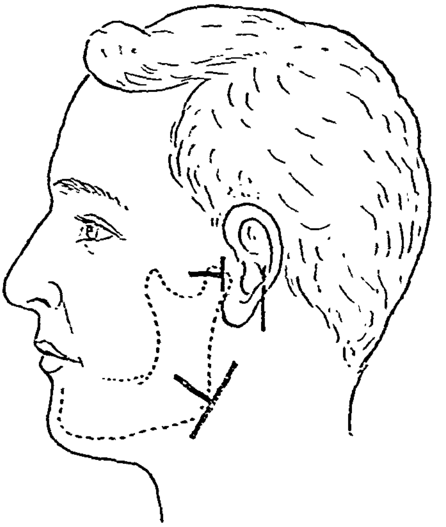
INFLAMMATIONS AND FISTULÆ OF THE SALIVARY GLANDS

AND THEIR TREATMENT.*

BY CECIL P. G. WAKELEY, F.R.C.S. ENG., F.R.S. EDIN.,
ASSISTANT SURGEON AND LECTURER ON SURGERY, KING'S COLLEGE HOSPITAL; ASSISTANT SURGEON, BELGRAVE HOSPITAL FOR CHILDREN.

THE parotid, submaxillary, and sublingual glands are all developed from the lining epithelium of the primitive mouth in essentially the same manner. The primordium of each gland is originally a solid cord of cells growing from the epithelium into the underlying mesenchyme. The cords branch and subdivide, lumina appear, and the apices of the terminal ducts finally become dilated to form acini. The proximal portion of the original outgrowth becomes the main duct. The rudiment of the parotid appears in embryos of 10 mm.—that is, about the sixth week of intra-uterine life. It commences near the angle of the mouth in the upper alveolo-labial sulcus, grows backwards over the outer aspect of the masseter muscle, the external carotid artery, the temporo-maxillary vein, and the facial nerve; it finally expands in the recess between the lower jaw and the meatus and mastoid process. The submaxillary and sublingual glands appear later as outgrowths from the epithelium lining the alveolo-lingual groove in the floor of the mouth, at about the 11 and 12 mm. stages, that is about the seventh week of fœtal life. Whether the salivary glands are derived from ectoderm or entoderm is a question to which no certain answer can be given. If all structures developed from epithelium covering the maxillary and mandibular arches are ectodermal in origin, then the parotid glands, anterior part of the tongue, and the floor of the mouth and presumably also the submaxillary and sublingual glands, are derived from ectoderm, although some authors contend that the last named are entodermal. Mucin cells do not appear until the sixteenth week of fœtal life.

FIG. 1.



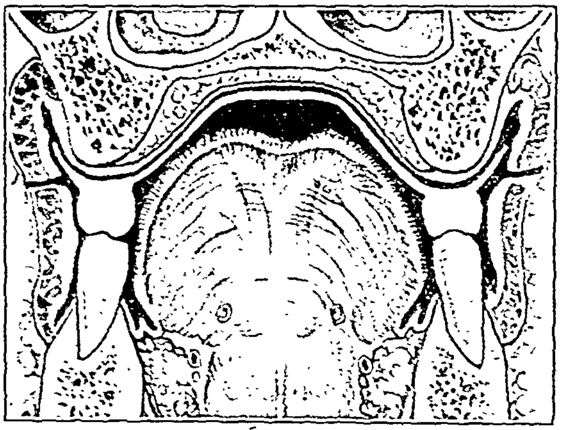
Incisions used in the treatment of suppurative parotitis.

Complete absence of the salivary glands is a very rare condition. Xerostoma or dry mouth may occur in children and adults, occasionally in several members of the same family. This is not due to absence of the salivary glands, but to suppression of the glandular secretion.

Suppurative Parotitis.

This condition is, in my experience, most frequently met with in the insane, especially in those who have to be forcibly fed by the mouth or nose. These patients always have dry mouths, even when food is being administered. There is a definite lack of psychical juices and of appetite, and indeed a definite feeling of repulsion for food. Infection reaches the parotid via Stenson's duct, and the first sign is usually swelling and fluctuation of the gland. General resistance on the part of the patient is so poor that the temperature and pulse exhibit very little variation from normal. If early incisions are not made the pus finds its way to the surface by bursting into the external auditory meatus at the junction of the osseous and cartilaginous portions. These cases are nearly always fatal unless free incisions are made into the gland. The gland itself undergoes necrosis and large sloughs are formed; these should always be removed.

FIG. 2.



Section through the mouth showing the relation of an upper denture to the parotid duct on each side.

Cope[1] reported seven cases of acute necrotic parotitis which occurred in debilitated soldiers in Baghdad during the extremely hot summer of 1917. These cases appear very similar to those which occur in mental institutions in this country. Early free incisions are imperative; mere puncture of the gland or probing it with sinus forceps is useless. The incisions advocated by Legg and Cope are very useful and allow of free drainage (see Fig. 1). Even when drainage is established the mortality is high, mainly owing to the lack of resistance. The administration of rectal and subcutaneous saline is impossible in mental cases. The author has seen ten cases among patients suffering from a depressed confusional state associated with delusions. Of these eight died.

Post-operative Parotitis.

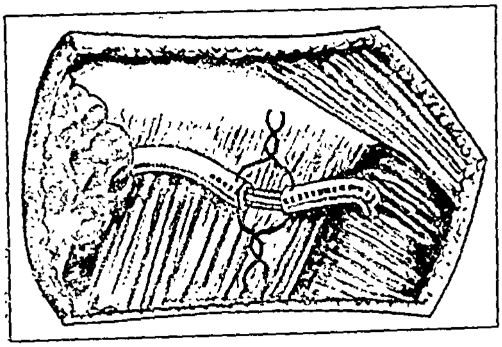
This is now becoming rare, and as its pathology is known it should disappear entirely. In 10,210 operations performed at King's College Hospital between 1900 and 1910, 32 cases (0·313 per cent.) of parotitis occurred, all after laparotomies, while in 17,585 operations performed at the same hospital between 1918 and 1927 there were 18 cases (0·102 per cent.) of parotitis. This reduction is due to the fact that gastric and abdominal cases are more carefully prepared, and that rectal saline, with or without potassium bromide, is administered in almost every case. Further, oral sepsis is now treated before any abdominal operation is contemplated, while before 1910 oral sepsis was neglected and dental treatment was almost unheard of in the wards of a hospital. Wagner,[2] writing in 1904, stated that the mortality of post-operative parotitis was 30 per cent. In my first series (i.e., 1900 to 1910) the mortality was 37·5 per cent., while it has dropped in the second series (i.e., 1918 to 1927) to 16·6 per cent. This reduction is due to earlier operative interference in the way of incision and drainage. Incision should not be delayed until fluctuation can be elicited. It is only in the later stages of suppurative parotitis that fluctuation can be made out; this is due to the fact that the parotid is encased in a very firm capsule derived from the cervical fascia, and the texture of the gland is very firm. A ⊥-shaped incision should be made and the skin and parotid capsule incised; the gland should then be explored with a pair of sinus forceps or a probe. A single ⊥-shaped incision is often sufficient, but at times multiple incisions are necessary.

---

* Abstract from Erasmus Wilson lecture delivered at the Royal College of Surgeons of England on Feb. 22nd, 1928.

The total amount of saliva secreted in the 24 hours has been estimated at 2000 c.cm. If the parotid glands are responsible for half of this, one gland would secrete 500 c.cm. in the 24 hours or just over 20 c.cm. in an hour. Thus there is a continuous stream of secretion flowing down the parotid duct, and infection from the mouth is almost impossible in normal individuals. Should any factor interfere with this secretion the liability to infection increases. There can be little doubt that the vast majority of cases of post-operative parotitis are caused through infection passing from the mouth via Stenson's duct to the gland. This is borne out by the figures I have given and also by Fenwick's [3] results published in 1909 of the treatment of 300 cases of hæmatemesis by rectal feeding. He allowed his patients to suck an indiarubber teat, and did not have a single case of inflammation of the parotid gland. Rolleston and Oliver [4] found that in the medical treatment of 1000 cases of gastric ulcer the percentage of parotitis in the cases which are treated by oral starvation is 4·5 per cent., while the percentage is only 0·4 per cent. in the cases which are allowed fluid by the mouth. Fisher, of Ohio,[5] however, considers that post-operative parotitis is hæmatogenous, and that the predisposing factors are cachexia and malnutrition, causing a lowering of the patient's resistance. He also believes that "the secretion of the gland is under the influence of nerve stimuli, and that the incidence of post-operative parotid involvement is neurologically dependent upon surgical shock or inhibition of the secretory and trophic fibres from higher psychic centres." This opinion does not seem to me to be physiologically sound, as the secretion of the parotid is probably dependent on two factors only: nervous and chemical stimulation. That the second exists is proved by the fact that if the nerve supply of the gland is cut off secretion still continues, a so-called paralytic secretion which is the result of chemical stimuli (vide infra).

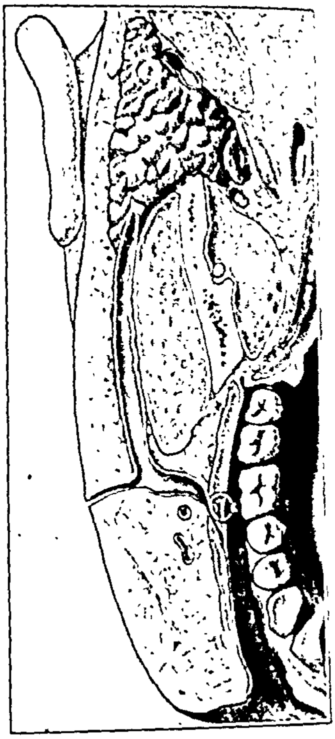
FIG. 3.



Method of suture in cases of recent injury to the parotid duct. A piece of silkworm gut acts as a dowel.

Occasionally unilateral or bilateral parotid swellings are due to a large upper denture which causes irritation of the gums and obstruction of the orifice of Stenson's duct. The first case that came under my observation was a woman aged 45 who had an upper denture fitted, and after wearing it for two days came up to hospital complaining of a swelling of the face and limitation of movement of the jaw. Her history was that the swelling began during breakfast and gradually increased in size. Distinct lobulation of the parotid gland could be felt, and Stenson's duct could easily be traced across the cheek. The orifice of the duct in the mouth was difficult to find, but while looking for it and at the same time pressing on the duct a plug of mucus was expelled into the mouth; this was followed by a flow of saliva and the disappearance of the parotid swelling. My curiosity was aroused by this case, and I looked up the literature and found that Jardet [6] recorded four cases occurring in adults in 1920. The condition is generally due to a badly-fitting denture (Fig. 2) which is not cleansed daily. The remedy is a properly fitting denture combined with the use of a potassium chlorate mixture, as this salt is excreted via the saliva.

FIG. 4.



Method of forming a new opening into the mouth by means of a suture through the buccal mucous membrane.

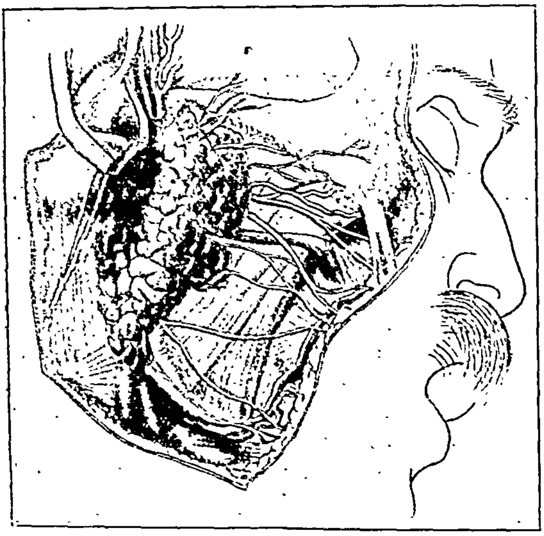
Fitzwilliams[7] has recorded an interesting condition of emphysema of the tissues of the face and neck which is brought about by inflation through the ducts of the salivary glands. Apparently self-inflation was a common form of malingering among the Chinese labour battalions in France during the Great War. The men would fill their mouths with as much air as possible and then strike their cheeks rapidly; this caused air to be forced gradually along the ducts and into the smaller canals of the glands. These small canals became greatly swollen and burst in places, allowing air to escape into the tissues. According to Fitzwilliams no alarming symptoms resulted, nor were there any after-effects; the emphysema rapidly disappeared. I have tried the experiment on dogs by passing a cannula into the parotid duct, and find that it is very easy to produce emphysema of the face and even half the body, the amount of emphysema being proportional to the amount of air forced along the duct and the pressure exerted. The symptoms are alarming at first, but usually disappear by the following day.

Salivary Fistulæ.

The only fistulæ of practical importance are those in connexion with the parotid and its duct. Fistulæ of the submaxillary gland tend to heal of their own accord; the rare cases which do not are easily treated by excision of the gland. Parotid fistulæ may be divided into two groups: (1) fistulæ of the duct, (2) fistulæ of the gland.

Fistulæ of the parotid gland and duct are most frequently caused by injury or suppuration around a calculus. Operations for removal of glands in the upper part of the neck may cause injury to the lower part of the parotid. A small fistula may result which tends to heal at once; if, however, the wound becomes infected a permanent fistula invariably results. The nearer fistulæ of the parotid are to the gland the more difficult they are to cure. They never tend to heal spontaneously, and the portion of the duct in front of the fistula frequently becomes stenosed and sometimes obliterated. Should the fistula be situated in front of the masseter muscle operation will often cure. In recent cases, such as a stab injury, the wound should be opened up and the two ends of the duct isolated.

FIG. 5.



Dissection of side of face showing the relations of the facia nerve to Wharton's duct.

A piece of stout silkworm gut is passed from the mouth through the orifice of Stenson's duct and out on to the face; it is then passed into the proximal portion of the duct and thus acts as a dowel. The wall of the duct is sutured over the piece of silkworm gut, and the skin wound closed. In order to prevent a clot forming in the duct at the line of suture the silkworm gut is retained in situ until the patient recovers from the anæsthetic. This method is only of use when the wound is recent (Fig. 3). Tees[8] advocates the use of catgut to act as a dowel, but the catgut swells and may cause complete blocking of the duct. If in a recent case there is difficulty in getting apposition of the divided ends of the duct the proximal portion should be ligatured; in the absence of sepsis this will cause atrophy of the parotid. If, however, infection is present septic parotitis will follow. Treatment by the ligature method is far from new and has recently been revived by Morestin[9] in France.

FIG. 7.

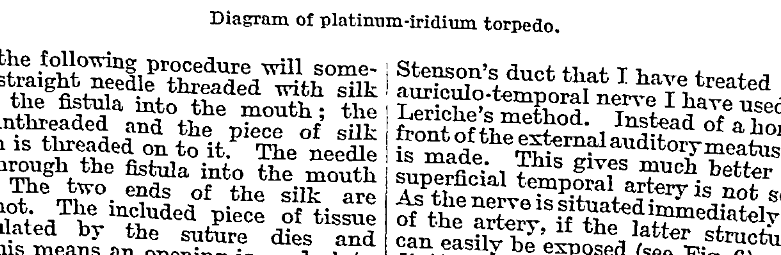


Diagram of platinum-iridium torpedo.

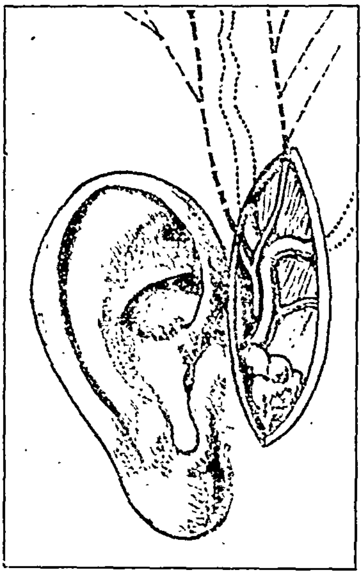
In old-standing cases of premasseteric fistula the following procedure will sometimes suffice. A straight needle threaded with silk is passed through the fistula into the mouth; the needle is then unthreaded and the piece of silk outside the mouth is threaded on to it. The needle is then inserted through the fistula into the mouth a second time. The two ends of the silk are then tied in a knot. The included piece of tissue which is strangulated by the suture dies and sloughs, and by this means an opening is made into the mouth. As the parotid secretion has now a free vent into the mouth the fistula heals (Fig. 4).

Fistulæ of the parotid duct which are situated in the proximal part—namely, over the masseter muscle—are, as may be imagined, very difficult to cure, and nearly 30 different operations have been devised. Most of them leave considerable scarring on the face, frequently damage the lower branch of the facial nerve, causing paralysis of the muscles at the angle of the mouth, and rarely cure the condition (Fig. 5). To my mind there is only one justifiable procedure, and if this fails, the secretion of the parotid should be cut off by dividing the auriculo-temporal nerve. The procedure is an old one, but is much neglected at the present day, when operative interference for every condition is carried out only too frequently. By means of a small fine malleable probe which is passed from the mouth along the duct and out of the fistula on to the face, a piece of silk is attached and drawn out on the face. To the end of the silk is attached a fine piece of drainage tubing, and this is drawn out of the fistula, leaving one end in the mouth while the other is projecting on the face. Saliva may find its way along the side of the drainage-tube into the mouth. After a few days the drainage-tube is drawn so far into the mouth that it no longer projects from the fistula. Finally after a week it is withdrawn altogether. In some cases the result of this method is admirable and the fistula remains completely closed; should infection of the duct be present, however, the rubber tube may cause parotitis.

FIG. 6.

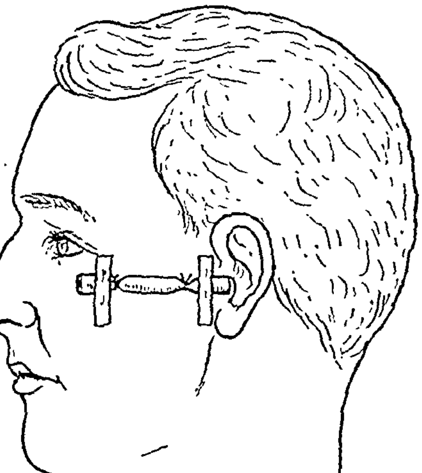


Method of exposing the auriculo-temporal nerve. It can be seen lying just behind the superficial temporal artery.

There is only one certain method of closing a fistula of Stenson's duct when sepsis is present, and that is by division of the auriculo-temporal nerve. This method was first advocated by Leriche[11] some 15 years ago. Since that time several surgeons, among whom Morestin[9] and Ferraini[12] may be mentioned, have given this method a good trial with excellent results. In the seven cases of fistulæ of Stenson's duct that I have treated by division of the auriculo-temporal nerve I have used a modification of Leriche's method. Instead of a horizontal incision in front of the external auditory meatus, a vertical incision is made. This gives much better exposure, and the superficial temporal artery is not so liable to injury. As the nerve is situated immediately in the deep aspect of the artery, if the latter structure is retracted it can easily be exposed (see Fig. 6); the nerve is then divided with a knife, the proximal portion grasped with a pair of Spencer-Wells' forceps, and as much of it as possible avulsed by firm traction. The fistula healed quite quickly, and after a month the amount of secretion coming via Stenson's duct into the mouth was reduced by one-half. Even division and avulsion of the proximal end of the auriculo-temporal nerve does not cause complete cessation of secretion of the parotid gland. Further, the secretion, which may be termed a paralytic secretion, persists for years, the longest period of which I have a record being six years.

The presence or absence of secretion from the gland is investigated by applying a little citric acid to the tongue and side of the mouth. If the gland is secreting a drop of saliva can always be seen at the papilla on the inside of the cheek. The secretion after division of the nerve is always much less than that of the other side, but the methods of observation in human subjects are not very accurate. One would hesitate to place small cannulæ into the orifices of both parotid ducts and try and collect the saliva therefrom; the risk of infection and its aftermath, septic parotitis, is too great. The most likely cause of the paralytic secretion is chemical stimulation. It may therefore be assumed that the normal secretion of the parotid is not only dependent upon the secreto-motor nerve-supply, but also upon some chemical stimulation. Langley has suggested that a local nervous mechanism may be responsible, but more recently McDowall[13] has pointed out that the activities of the parasympathetic are apparently the same as that of alkali, as judged by the effect on the heart, the pupil, and the blood-sugar. He states that this effect of alkali appears to be increased when the nervous connexions of the organs are increased. It may be, then, that when the nervous control of the gland is removed the normal alkalinity of the blood is sufficient to maintain secretory activity.

FIG. 8.



Method of applying radium to parotid fistula.

Fistulæ of the Parotid.

Fistulæ of the parotid gland tend to heal of their own accord. For those which do not the two methods of treatment are: (1) Radiotherapy, and (2) avulsion of the auriculo-temporal nerve.

Radiotherapy rarely fails to cure and is quite simple; 250 mg. of radium is enclosed in a platinum iridium torpedo, the thickness of which is 0·5 mm. The torpedo itself is encased in another platinum tube, 0·5 mm. in thickness, in order that the beta radiations may be cut off. The platinum tube is then placed in a rubber tube to facilitate its application (Fig. 7). The fistula and its surrounding parts are covered with lint, in order to cut off any secondary radiations from the metal filters (Fig. 8). A four-hour application is usually sufficient, but should the skin be somewhat thickened and indurated from the constant discharge of saliva, a six-hour application is advisable. Whatever length of application is used, it is advisable to give a hypodermic injection of atropine (gr. 1/100) half an hour beforehand: this lessens the secretion of the gland during the time the radium is being applied.

X rays have been used in the treatment of parotid fistulæ but are not so constant in their action. Three pastille doses, with a weekly interval between each, should be given through a filter of 3 mm. aluminium. Here again atropine should be administered prior to each treatment.

Should this method fail, avulsion of the auriculo-temporal nerve should be perfoimed.

THE RHEUMATIC LUNG.

BY A. E. NAISH, M.B., B.CHIR. CAMB.,
F.R.C.P. LOND.,
PHYSICIAN, SHEFFIELD ROYAL HOSPITAL.

(WITH COLOURED PLATES.)

THE term "Rheumatic Pneumonia" is an old one and was more in vogue in the medical literature of a past generation than of to-day. Possibly this is because the acute rheumatic fever of adults is now less common.

The condition I am about to describe contrasts so much clinically with what we usually know as pneumonia, that I prefer to use the simpler term, "rheumatic lung."

The microscopical appearances of these consolidations (1) indicate an inflammatory reactive process; (2) are unlike anything hitherto described in the human lung; (3) are remarkably constant from case to case; and (4) bear a strong resemblance to the lesions described by Aschoff and Tawara,[1] Carey Coombs,[2] and others, as pathognomonic of rheumatic infection in other parts of the body. If these contentions can be established, we have not only a demonstration of an entirely new type of inflammation of the lungs, but also a strong confirmation of the thesis advanced by Carey Coombs that the lesions of "rheumatism" (childhood type) show a specific form of reaction and therefore indicate probably a specific virus.

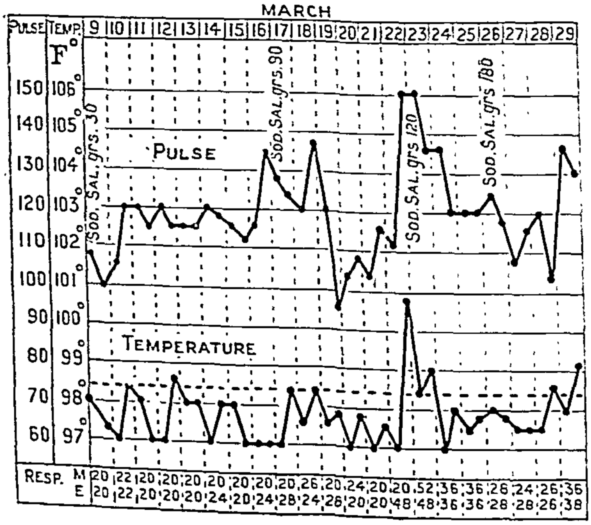
During the past two and a half years I have obtained post-mortem material from six of my patients who have displayed this peculiar consolidation of the lungs. Not all were children, their ages being respectively 7, 8, 9, 13, 26, and 33; but all gave evidence of active rheumatic infection, with the possible exception of the woman of 33, who had mitral stenosis, but whose heart muscle was unfortunately not examined to determine the presence or absence of Aschoff's nodules.

I propose to deal first with the general clinical aspect of this condition, then to describe the naked-eye and microscopical appearances of the lungs, and finally, after a brief description of the individual cases, to summarise and discuss my conclusions.

General Clinical Considerations.

Those who have experience of disease in childhood are familiar with certain more or less extensive patches of dullness which are liable to appear over the back of the chest in children suffering from active rheumatic carditis. They appear insidiously, being frequently unaccompanied by pyrexia or noticeable increase of respiratory-rate, and are therefore only detected by routine examination. Cough is sometimes present at the onset, but is of a mild variety and attracts little attention in a patient already seriously ill. The dullness sometimes appears quite rapidly, extending perhaps over the greater part of one lobe in the course of two or three days; it then may remain stationary over a long period lasting into months, and, finally, may clear up as rapidly as it began. The breath sounds over the dull area are often loudly bronchial, but there is every grade between this and muffled or completely absent respiratory sounds. During the quiescent stage no adventitious sounds are heard, but if the stage of onset is observed a few soft crepitant sounds are not infrequent.

It has been held by most observers that this dullness is present at the left base only, and, following the old observation of Bamberger[11] that dullness in this situation is common with pericardial effusion, the condition is usually considered to be a collapse of the lung due to the pressure of an enlarged heart or distended pericardial sac. My own observations, however, spread over a number of years, directly contradict the belief in the immunity of the right lung. It is true that the dullness usually begins at the left base and is most intense in that situation, but careful percussion will often reveal slighter dullness and altered breath sounds on the other side, and in a few cases the dullness is most intense on the right. It was, in fact, this last observation that first made me seriously doubt the current theory of collapse, and it will be seen from the post-mortem reports of the six fatal cases that in all of them the right lung was affected, and to about the same extent as the left. The reason for the earlier appearance and greater frequency of left-sided affection will be discussed at the end of this paper.



Although this condition appears only in those severely affected by rheumatism, yet it does not usually appear to add much to the gravity of the prognosis, and the great majority live for the dullness to clear up. The cases recorded in this paper showed a much more rapid extension of the dullness than is seen in the average case, and the symptoms were naturally more acute, but even in these it was remarkable how little the temperature and respirations were affected by the onset of the lung consolidation.

Take, for instance, the case of W. W. (see Chart), who had been in bed, under observation, for six weeks previous to the first appearance of a small patch of dullness at the angle of the left scapula on March 25th. Although the dullness increased at such a rate that by the 29th the whole of both sides, back and front, appeared to be dull, yet the respirations were for the greater part of these four days between 24 and 28 per minute, and the pulse-respiration ratio was approximately 4½ to 1. The temperature showed a brief rise on March 22nd, three days before any lung dullness was detected, but during the period when the dullness was so rapidly extending, the temperature was mostly subnormal. With regard to the temperature it must be noted that most of the patients were taking salicylate of soda, and that E. W., who was not, showed a temperature quite comparable to that of an ordinary pneumonia. In spite of this she, in common with the other patients whose temperatures were low, showed a p./r. ratio of approximately 4 to 1. The respirations were not only slow but there was scarcely any respiratory distress throughout the series of cases; the one definite exception being the case of I. D., in whose pericardium there was half a pint of fluid.

Cyanosis was very noticeable during the last day or two of life in those patients whose lungs were nearly solid throughout, but the amount of lung solidification in proportion to the degree of intensity of respiratory symptoms was throughout the series a surprising phenomenon.

Morbid Anatomy.

Macroscopical.—The extent of the pulmonary consolidation was a remarkable feature. In one case (W. W.) the only aerated parts seemed to be a strip along the anterior border of each lung, and most of the right middle lobe. In another (I. D.) all parts of both lungs were affected, but the upper lobes appeared to contain some air. In another (E. C.) the right lung was completely solid throughout, but the left, though very largely solid, floated in a submerged position in water. In another (A. B.) three-quarters of the right lung and a quarter of the left lung were solid. The other two showed consolidation of both lower lobes. There was no sharp demarcation between solid and air-containing lung.

The appearance of the affected parts was quite characteristic and unlike that seen in any other form of pneumonia. Its consistency was not unlike that of solid indiarubber, very tough, and non-friable on the cut surface. The colour, on section, was a shade of purplish red, quite homogeneous in tint and showing none of the "granite" or "marbled" appearance of other pneumonias. Scraping with the knife produced no exudation. In one case the bronchi exuded a blood-stained fluid on pressure.

So characteristic were the naked-eye appearances that in the case of E. W. the condition was recognised at once by our pathologist, although she had seen only one case previously.

Microscopical.—Before describing the microscopical appearances I will quote from Coombs'[3] description and explanation of the submiliary nodules of the heart.

> "The nodules consist of a groundwork of fibrin, surrounded and interrupted by various cells. Of these, the most important are certain large cells which form the characteristic feature of the nodule; there are also leucocytes and plasma cells."
>
> "The characteristic large cells vary a little in shape according to the shape of the space in which the nodule develops; in rounded nodules the cells are often globular, but even in such they may be fusiform, and this is the form they tend to take. That they are soft is shown by their taking shape from one another so as to give flat sides and quadrilateral outlines to each. The largest cell is of such a size that, measured from pole to pole, it is equal to one-third or one-quarter of the diameter of the microscope field, as seen with 1000 magnification. Its cytoplasm, which is very finely granular, takes both basic and acid dyes readily, so that the cell is a dark object in the field. In some the cytoplasm looks opaque and the cellular outline is apt to

be lobular; such cells are probably being destroyed by toxins, perhaps by those which call them into being. There may be as many as seven nuclei in one cell, apparently without any plan of arrangement; though as many of the cells are so narrow that they can carry but one nucleus abreast, they lie in a sort of chain along the long axis of the cell. The chromatin thread of the nucleus stains sharply with hæmatoxylin, each nucleus appears as a space bounded by a thin black line and clear centrally except for several sharp black dots which represent cross-sections of the chromatin thread.

"The stages of the tissue reply to irritation by the *Streptococcus rheumaticus* would appear to be as follows: First, the endothelia of the smaller blood-vessels and lymphatics proliferate; this is manifested in partial or complete occlusion of vessels, with or without thrombosis, in the dissemination of "endothelial leucocytes," which are mainly collected in perivascular foci, and in the building up of new capillaries. Second, the perivascular connective tissues display a fibroblastic reaction, especially around the newly formed capillaries. Third, leucocytes arrive in the disturbed area; in most areas the polymorphonuclears are represented but sparingly, but the more severe the attack, the more likely they are to appear, and in some spots they even dominate the picture, especially where large vessels are closed by inflammatory thrombosis. The usual appearances, therefore, are those of a blood-borne infection of a virulence so moderate that it is for the most part dealt with successfully by the first line of defence—the vascular endothelia."

On comparing under the low power sections of the lungs from my cases with those from a lobar or broncho-pneumonia, certain contrasts are seen at once.

PLATE I. is from a typical broncho-pneumonia and shows large alveolar cavities with thin walls, the cavities being nearly filled with a mass of fibrinous exudate and polymorph leucocytes slightly shrunken away from the walls, and such red blood corpuscles as are present in the walls are nearly all contained within small vessels.

PLATE II. is a microphotograph from W. W. (Case 6). The alveolar walls are seen to be some 8 or 10 times as thick as in the former plate; the red blood cells are not contained within vessels, but are widely diffused among the other cells of the walls; the cavities of the alveoli are quite small and are encroached on by small outgrowths from the walls.

PLATE III. shows: (1) proliferation of the endothelium lining a capillary; (2) outgrowth of similar endothelial cells in all directions, so as to make it difficult to distinguish wall from cavity; and (3) general diffusion of red blood cells among the endothelial cells.

PLATE IV. enables us to see the cells which are in all parts of the section like those described by Coombs.

These cells form the immensely thickened walls and are seen budding out in little tufts into cavities of the alveoli. In some places the walls can be traced with fair ease, but in others, where apparently the process has reached a more advanced stage, the alveolar structure has been entirely replaced by masses of these cells, either packed closely together or drawn out into a syncytioid mass. Multinucleate cells are fairly frequent, though I have not found any cells with more than five nuclei. In all but one of my cases these endothelial cells form the vast majority of the structure, being mixed with only a few fibroblasts and polymorph leucocytes, but in one (J. J. C.) the polymorphs were quite numerous, though even here there was the same massive endothelial background on which the leucocytes were dotted. A still later stage of the process shows the endothelial cells beginning to form new blood-vessels. In one very acute case the mediastinal glands were enlarged and very red, and sections showed not only a notable vascularity but the invasion and replacement of considerable areas of lymphoid structure by endothelial cells of the same type. In cases where the heart muscle was cut, typical Aschoff's nodules were found.

The following is the description kindly written for me by Dr. Clara Tingle, pathological assistant to the Sheffield Royal Hospital.

"Large endothelial cells are the predominating ones found in this condition. They are constantly present and in large numbers. The average diameter appears to about 4–6 times that of a red cell, but they vary according to the pressure put upon them by surrounding structures. The majority of these cells are mononuclear, the nucleus being equal in diameter to about one-third the diameter of the cell. Many cells, however, are multinucleated, there being in some instances as many as five or six nuclei per cell. In these "giant cells" the nuclei are separate from one another and are arranged irregularly within the cell. The nuclei always appear as a dark-staining ring with a central space, which often is unstained but which sometimes shows darkly staining dots. The cytoplasm stains deeply and is faintly granular. Sometimes carbon pigment is found within the cells. (I have not found any showing active phagocytosis to other cells.) In areas where these cells are fewer in number they tend to be wholly within the alveolar walls, causing thickening and distortion of these structures, but in areas where the change appears more advanced the cells lie in large numbers within the alveoli. They are accompanied by red blood cells and a few plasma cells, and the alveolar contents do not tend to retract from the walls during preparation of the section as they do in lobar or broncho-pneumonia. There are also found a few areas in which the lung structure is completely lost and is replaced by a mass of these cells separated only by red blood cells, plasma cells, and a few fibroblasts."

Individual Cases.

The following are short descriptions of individual cases:—

CASE 1.—I. D., male, aged 8. Admitted Dec. 9th, 1925; died Dec. 19th, 1925. Onset two months ago: pain in the left chest and back; sweating; frequent abdominal pain; occasional joint pain; always tired; dyspnœa on exertion; no sore throat.

On admission: Tongue furred; immense tonsils; muco-purulent discharge from the naso-pharynx; no nodules; no pallor. Heart: There is much visible pulsation; the left border 5 in. from the middle line; systolic and diastolic murmurs at the apex. Lungs: Crepitations and slight dullness at the left base.

Dec. 15th: Heart breadth 6½ in.; pericardial friction. 17th: Dullness and crepitations at right base. From this time onwards increasing respiratory distress and inability to lie on left side.

Pulse-rate: Varied from 120 to 145 throughout stay in hospital. Temperature: 100·4° F. on admission, slowly falling to normal on the 13th; on the 15th it rose again to 101·2° F., falling to normal on the 17th. Respirations: From Dec. 9th to 15th, 20 to 36 per min., the average being about 28. From Dec. 15th to 18th, 36 to 40 per min., and within the last 30 hours before death rising rapidly to 78. P./r. ratio approximately 4½ to 1 up to the 15th and from then 3¾ to 1 to the day before death.

Autopsy.—Pericardium contains half-pint of clear fluid; small area of fibrinous exudate on the anterior surface of the right ventricle; the whole of the pericardial surface slightly dulled. Tricuspid and mitral and aortic valves show small pale vegetations, on the two former valves in the form of long narrow bands on the auricular surfaces, but on the aortic in the form of groups in the centre of the ventricular surface of each cusp. Lungs: Massive consolidation of the whole of both lungs, but some air can be squeezed from both upper lobes; the consolidation is of india-rubber consistency; non-friable; purplish red; cut surface not like granite.

CASE 2.—E. W., female, aged 26. Admitted Jan. 13th, 1926; died Jan. 17th, 1926. Had rheumatism and chorea in childhood. Run down and lost weight for one year. Seven weeks ago taken ill with pain first in the back and then in the right side of the chest; sweating; in bed for two days; then up for seven days; relapse for ten days with cough and slight delirium added; again three weeks up and about; then, on Jan. 12th, 1926, temperature rose.

On admission: Breathing quite comfortably and without distress. Heart: Rapid; size not determined owing to dullness of the left lung. Lungs: Dullness at both bases; breath sounds weak at the right base; bronchial breathing at the left base.

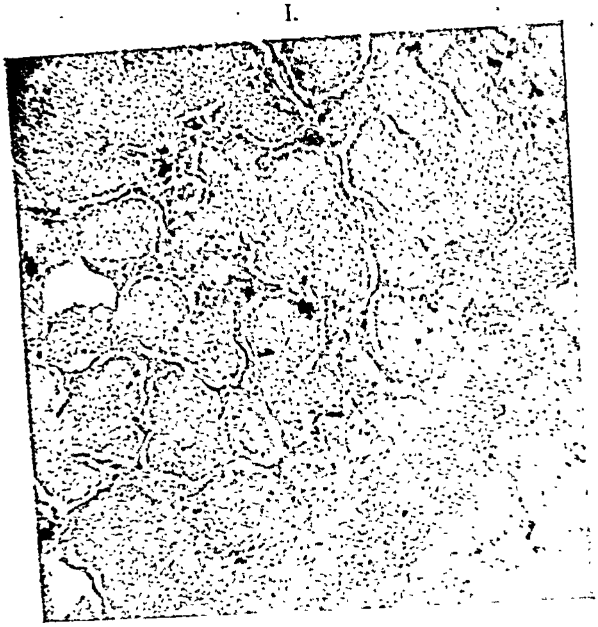
Progress: Spread of the dullness, especially on the right: bilateral friction; jaundice by the 15th; never any respiratory distress.

Pulse-rate from 120 to 150. Temperature from 101° to 105°. Respirations from 28 to 36; above 36 only during the last 24 hours of life. P./r. ratio approximately 4½ to 1 during first three days; 3¾ to 1 during last 24 hours before death.

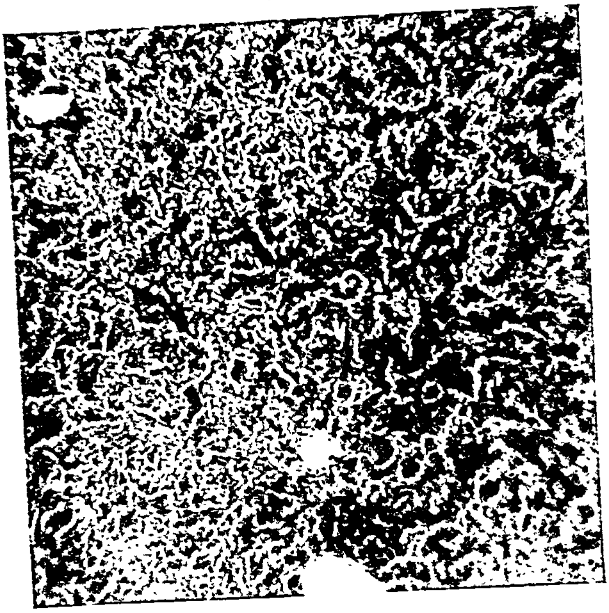
Autopsy.—Pericardium: Fibrinous pericarditis with recent adhesions; hypertrophy of the left ventricle; old mitral stenosis; a few small pale vegetations over auricular surface of mitral valve. Lungs: A little fibrinous pleurisy at both bases; both lower lobes airless; upper lobes congested; bronchioles exude blood-stained fluid on pressure. The consolidated part india-rubber like; very tough; non-friable; homogeneous in colour.

DR. A. E. NAISH: THE RHEUMATIC LUNG.

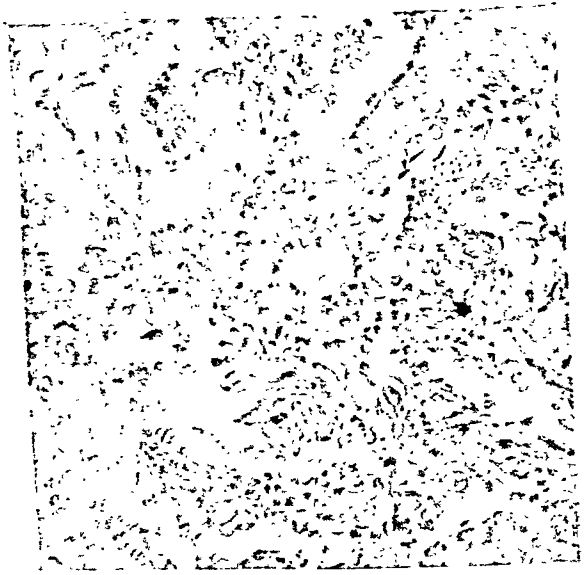
I.



II.



III.



IV.

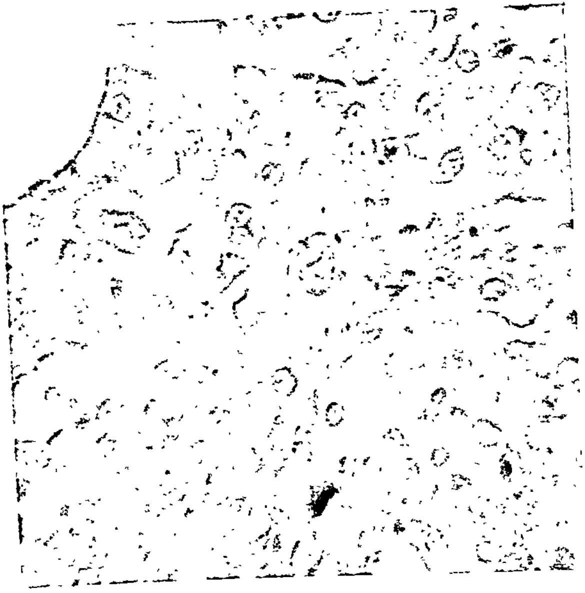


Plate I. (× 60) is from a typical bronchopneumonia and shows large alveolar cavities with thin walls, the cavities being nearly filled with a mass of fibrinous exudate and polymorph leucocytes slightly shrunken away from the walls, and such red blood corpuscles as are present in the walls are nearly all contained within small vessels.

Plate II. (× 60) is a microphotograph from Case 6. The alveolar walls are seen to be some 8 or 10 times as thick as in the former plate; the red blood cells are not contained within vessels, but are widely diffused among the other cells of the walls; the cavities of the alveoli are quite small and are encroached on by small outgrowths from the walls.

Plate III. (× 280) shows: (1) proliferation of the endothelium lining a capillary; (2) outgrowth of similar endothelial cells in all directions, so as to make it difficult to distinguish wall from cavity; and (3) general diffusion of red blood cells among the endothelial cells.

Plate IV. (× 520) shows in all parts of the section the characteristic large cells described by Coombs.

CASE 3.—E. C., female, aged 13. Admitted March 13th, 1926; died March 20th, 1927.

December, 1926: Sore throat and pain in the knees; was in bed two weeks and afterwards was kept from school. Feb. 17th, 1927: Came to the out-patients' and was advised to stay in bed. March 7th: Much worse; weakness and pain in the knees.

On admission: Pallor. Heart: Dullness 1¾ in. to the right and 5 in. to the left of the middle line: systolic and diastolic murmurs at the apex. Lungs: No dullness detected.

March 18th, 1927: Vomiting; cyanosis; restlessness; pain: dullness at the left base; pericardial friction; liver very large. March 19th: Dullness at right and left bases, which subsequently increased rapidly.

Pulse-rate, 100 to 120. Temperature on first two days after admission, 98·8° F.; after that, never above 98·4° F. Respirations up to the 16th, 20 to 28, afterwards 22 to 40. P./r. ratio approximately 4½ to 1, except for a brief period about 24 hours before death.

Autopsy.—Pericardium: A little fibrinous exudate about origins of great vessels and less at apex; about 2 oz. fluid in sac. Heart: Muscle flabby and mottled; moderate dilatation: small vegetations at bases of aortic cusps and on auricular surfaces of mitral and tricuspid valves. Lungs, pleuræ: A little fibrinous exudate at right base: whole of right lung solid: sinks in water; tough, non-friable; non-granite-like. Left lung similar but less affected, many parts floating; consolidation not circumscribed.

CASE 4.—A. B., female, aged 33. Admitted March 31st, 1927; died March 31st, 1927.

History.—Rheumatic fever at 7 years old; heart affected; very delicate since; frequent aching of limbs; pneumonia in 1922. Dec. 31st, 1925, became ill with bilateral chest pain and cough; admitted on Jan. 3rd, 1926, showing widespread râles, friction at left base, and double bruit over the cardiac apex. The râles cleared up within a week, leaving a patch of dullness, bronchial breathing, and increased vocal vibrations at the left base, which in turn cleared after a few days. The temperature was never above 100, and for a good part of the acute stage was subnormal. Respirations after first two days, 20. After this she returned to her usual state of invalidism. For a few days before death more dyspnœic but not laid up, and she actually walked up to the out-patient department on the day of her death.

On admission: No notes of importance, owing to her rapid death shortly after admission.

Autopsy.—Heart: Dilatation and hypertrophy of right ventricle and right auricle; dilatation of the left auricle. Mitral valve sclerosed; button-hole orifice admitting one finger. Pericardium, normal. Lungs: Consolidation of the whole of the right lower lobe and one-third of the right middle lobe; slight consolidation at the left base; consolidated parts show rubbery consistency, toughness, non-friability, and homogeneity of colour.

CASE 5.—J. J. C., male, aged 9. Admitted Sept. 7th, 1927; died Jan. 28th, 1928. Three years ago had an illness called pneumonia, since then has had pain in the left chest; dyspnœa on exertion; listlessness; poor appetite; sweating. Lately, bumping of the heart.

On admission: Languid; pale; sweating. Heart: left border 5 in. from the middle line; double bruit at apex, the diastolic murmur being loud. Lungs: nothing abnormal detected. During September vomited from time to time.

Oct. 3rd, 1927: Nodules on occiput, right wrist, left elbow, and left external malleolus. No evidence of pericarditis or pulmonary consolidation. Looked very ill. Respiratory average about 31. Antistreptococcal serum given on Oct. 10th, 18th, 25th, and Nov. 2nd. Nov. 14th: Much better, nodules nearly gone. Through the rest of November and December very well.

Jan. 7th, 1928: Pain in knees and chest; 9th, vomiting; 11th, rash of raised red patches, heart dullness 2½ in. to right and 5½ in. to the left of the middle line; 13th, dullness at left base, no bronchial breathing; 16th, 17th, 18th, and 23rd, antistreptococcal serum; 20th, dullness at the right base. Temperature range, after the 7th, was usually 99° to 100° F., but there was a rise on the 7th to 101·4° F., and another between Jan. 12th and 17th to a maximum of 101·6° F. Respirations from 23 to 32 up to Jan. 24th, after this 32 to 36. Pulse-rate averaged 120. P./r. ratio approximately 4 to 1 up to last 48 hours.

Autopsy.—Heart: very large; largest diameter 7 in. Right auricle much dilated; other cavities moderately so. Pericardium adherent; no recent pericarditis. Lungs: Complete consolidation both lower lobes; india-rubber consistency; non-friable; purplish-red, not mottled.

CASE 6.—W. W., male, aged 7. Admitted Feb. 14th, 1928; died March 30th, 1928. Movements for past two months.

On admission: Acute chorea; pallor; wasting; indifference to surroundings; nodules on right occiput, each elbow, near metacarpo-phalangeal joints and on dorsa of both feet. Heart: Breadth 4 in., soft-blowing apical systolic murmur. Progress: Steady improvement; after 2½ weeks, better colour; scarcely any chorea; appears plumper; taking interest and chatting.

March 16th: Pulse-rate went up and the cardiac dullness was enlarged by 1 in. 22nd: Rise of temperature; heart-rate, 160; respirations, 52; vomiting; diastolic bruit at apex. 25th: Small area of dullness at angle of left scapula; crepitations; respirations, 36. 26th: Dullness increasing; respirations, 28. 27th: Dullness and crepitations at right base; respirations, 24 to 28. After this very rapid increase of dullness. P./r. ratio very seldom below 4 to 1.

Autopsy.—Heart: Moderate dilatation of the right ventricle, left ventricle, and right auricle. Valves: Aortic and mitral, vegetations in groups along the line mid-way between attachment and free edge; mostly white, but small hæmorrhagic points. No pericarditis; no increase of pericardial fluid. Lungs: A few ounces of fluid in either pleural cavity. Nearly solid; only right middle lobe and anterior free edges showing any air. Consolidation is of india-rubber consistency; non-friable: purplish-red; cut surface, not like granite. Mediastinal glands: The size of beans; very red; semi-soft. Liver: Large and fatty. Mesenteric glands: Similar to mediastinal.

Discussion.

The appearance of the lungs in these cases is apparently quite different from anything that has been hitherto described. Dr. Robert Hutchison informs me that over 20 years ago the pathologist at the London Hospital, Dr. Salaman, prepared sections from the lungs of a rheumatic case and found similar appearances, but that the slides were lost. Pichon and Lardé-Arthés [4] have described what they call "multiple pulmonary infarcts" in association with active carditis, which will be referred to in a moment. Coombs, Miller, and Kettle [5] have described a remarkable endothelial proliferation of the vessel walls in the lungs of rabbits which have been inoculated with virus from rheumatic cases. Apart from this I have been unable up to the present to find any precise accounts in the literature of pathological examination of these pulmonary consolidations.

These lung appearances are strikingly like those described by Coombs [3] in cardiac submiliary nodules, the main difference being that they suggest an earlier stage of development in which endothelial proliferation entirely overshadows fibroblastic reaction. It is also to be noted that in the lung preparations there is evidence of considerable effusion of red blood corpuscles from the damaged capillaries, whereas this is not a feature of the submiliary nodules. This, too, I take to be an indication of an earlier stage of development before absorption of cells has taken place. The highly vascular nature of the alveolar wall must also be taken into consideration in making a comparison with the rheumatic lesion in other sites.

In this connexion it is interesting to bring forward microscopical appearances from another case to indicate that endothelial proliferation and effusion of red blood cells are closely connected. A girl of 17 years (D. Q.), under the care of my colleague, Prof. Arthur Hall, died on Nov. 5th, 1925, with pericarditis and pulmonary consolidation. The greater part of the lung section showed an ordinary broncho-pneumonic reaction with the red blood cells contained in little groups within the capillaries, but in certain small portions of the slide there was obvious blood effusion, and here the endothelial proliferation was most remarkable, the large cells budding out in long strings.

At this point I should like to discuss the case recorded by Pichon and Lardé-Arthés.[4] The so-called infarcts, which were scattered about in an irregular fashion through the lungs and had no sharp margin or definite shape, were attributed by the authors to rupture of vessels by high pressure (it was expressly stated that embolism or thrombosis of vessels was carefully looked for without success). The microscopical appearances are recorded very briefly; merely the words "Les alvéoles pulmonaires sont remplis d'hématies." When this case is compared with some of my cases which were very definitely hæmorrhagic, and in one of which blood could be squeezed from the bronchioles, it appears to me possible that a further examination of the sections might reveal in their case an earlier stage of the endothelial reaction to be at the bottom of the hæmorrhage. This seems to me especially likely, as the case showed a definitely febrile carditis, with Aschoff's nodules throughout the heart, and there was nothing in the notes to suggest very high venous pressure.

Another point that is worth discussing is whether the pulmonary consolidation in these fatal cases is the same as in the more familiar non-fatal cases. Careful consideration of the signs and symptoms of the two classes has led me to the belief that they are identical. There are obvious differences in intensity, but even the most acute display the same insidious onset and lack of disturbance of respiration up to the point when loss of aerating surface is extreme. In fact most of these pulmonary consolidations would have been missed during life had not my interest in the subject led me to frequent examination of the bases. Transition cases also are reported in the literature. Take, for instance, the small epidemic of six cases described by Cheadle[12] in 1888. In this are particularly noted the lack of cough, expectoration, and respiratory distress, but the inflammatory nature of the consolidation is indicated by a little rise of temperature, and the presence of some fine crepitant sounds on the day of onset.

Not all pulmonary complications of rheumatism are of the insidious type described above. Achard,[7] following Bernheim,[8] has distinguished three forms: acute general congestion, partial congestion, and latent congestion, but he does not particularise very carefully the respective cardiac states of the patients displaying these syndromes. Where high pressure is present in the pulmonary veins it is obvious that an important complicating factor cannot be excluded. My patient (A. B.), who had a fairly high grade of mitral stenosis, was in for so few hours during her fatal illness that no serious observations could be made; but a little more than a year before she had been under observation for a pulmonary complication. This started with bilateral pain, dyspnœa, cough, and cyanosis, and showed scattered râles all over both sides, but on this condition clearing up an apparent consolidation at the left base was left, the respiratory-rate being only 20. It seems to me likely that this left base consolidation was of the same nature as that which killed her a year later, and that the acute generalised signs and symptoms were produced at the onset of the specific rheumatic inflammation by reason of the high pulmonary venous pressure.

There comes now the question as to why the consolidation should so commonly start at the left base and in mild cases be confined to the region. Dr. Robert Hutchison and Prof. Langmead have suggested to me that it is by direct spread from the pericardium, the rheumatic organism having a tendency to transgress anatomical boundaries and spread by contiguity. The former has stated in one paper[6] that he has never found the condition except in association with active pericarditis.

A consideration of my cases shows that an active pericarditis was not always present in association with the consolidation; three out of the six had none. This I think renders the spread theory unlikely. For some time I thought that the pressure of a large heart and the consequent partial collapse of the left lung must be the factor determining the preference for this situation, but consideration of the very different sizes of the hearts in the affected cases has made me abandon this supposition.

My present position is rather to make a suggestion than to state a theory. It is now a well-known fact that the rheumatic reaction processes are most likely to be found in positions exposed to friction. Subcutaneous nodules appear in just those positions where the skin is liable to be rubbed over bony surfaces, and vegetations on the valves usually appear in positions where there is most chafing. I would suggest, then, that the large and rapidly beating heart does, by its local massage of the left lung, make that small difference which determines the seat of election. At the same time I would point out that the acute cases do not show any special predilection for one side, and I think that a careful clinical study of the more chronic cases will show that there has been an exaggeration of the unilateral incidence produced in our minds, probably by the suggestive influence of the collapse theory.

One of the difficulties which must be faced is how with so massive a change in the lung the normal parenchyma can be restored. The answer to this is bound to be speculative, but the remarkable power these endothelial cells have of regenerating new blood cells supplies a hint. In the older books the association of pneumonia and pleurisy with rheumatism was considered to be quite a well-established fact. A. E. Garrod,[9] in 1890, wrote a "Treatise on Rheumatism," in which he devoted a chapter to "rheumatic pneumonia," quoted statistics from a number of earlier authors, and made some very acute observations. Rheumatism then, however, was probably more common in adults and more acute in its manifestation, and, although these observations have great interest and value, it is necessary to cover the ground again and correlate physical signs and symptoms with what we have since learnt of the specific pathology of the condition.

There are other subsidiary questions which my sections serve, I think, to settle. For instance, Letulle, Bezançon, and Weil[10] have advanced a theory that the large multinucleate cells of the Aschoff nodule are derived from the muscle cell of the heart. The sections from my cases go far to disprove this.

Summary.

1. A new type of pathological consolidation of the lungs is described. 2. This consolidation is associated with evidence of active rheumatism elsewhere in the body and usually in the heart. 3. Its most striking feature is an enormous endothelial proliferation, the cells apparently originating from the walls of the alveolar capillaries. 4. The reactive process appears to be identical with that described by Coombs as pathognomonic of rheumatic infection elsewhere, and its specific nature is even more striking. 5. The consolidation may spread through the lungs with great rapidity. 6. There is very little disturbance of the respiratory-rate and scarcely any respiratory distress until the consolidation is enormous. 7. If salicylate of soda is given the temperature is little, or not at all, raised. 8. This type of consolidation probably accounts for the patches of dullness met with at the left base in association with rheumatic carditis and hitherto attributed to collapse from pressure.

In conclusion I should like to express my thanks to Dr. C. D. Tingle, assistant pathologist at the Royal Hospital, for invaluable assistance; to my colleague, Prof. Arthur Hall, for so kindly allowing me to examine the slides of his case, and for his valuable help in other ways; and to the Librarian of the Royal Society of Medicine, who has been indefatigable in helping me to trace references.

Clinical and Laboratory Notes.

A NEW METHOD OF ADMINISTERING HEAVY METALS.

WITH REFERENCE TO THE TREATMENT OF CANCER.

By J. Leon Jona, M.D. Melb., M.S. Adel.

(From the Physiological Laboratory, University of Melbourne.)

It sometimes happens that heavy metals given by the mouth either are not absorbed (cf. Bunge [1]) or produce irritation of the stomach or bowel. The consequent vomiting or diarrhœa causes the loss of a variable amount of the administered metal as well as general effects due to the gastro-intestinal disturbance. When the metals are injected subcutaneously or intramuscularly, local irritation or even death of tissue, with consequent inflammation, necrosis, or sloughing often results. When injected intravenously the metal is either (in all probability) combined with the proteins of the blood and then picked out by the liver and slowly excreted, or a violent effect on the heart or nervous system is produced by the sudden introduction of the toxic metal, and the recipient collapses or dies, according to the dose. So it occurred to the writer that the blood corpuscles might be utilised as a vehicle. Introduced metal-laden corpuscles break down at a steady rate, so that the metal is steadily liberated into the blood, probably as a colloidal compound, and picked out by those tissues having an affinity for it. That a metal so added to a corpuscle is apparently combined with or adsorbed to the envelope of the corpuscle can readily be seen by treating a smear preparation of corpuscles combined with lead, bismuth, copper, or mercury with a solution of sulphuretted hydrogen, when the red corpuscles show a black rim like the tyre of a wheel and the surface of the corpuscle is stippled or stained more or less uniformly black. The great surface-area of the corpuscles—about 600 sq. mm. in 1 c.mm. of blood—provides tremendous scope for medication. (See Tabulæ Biologicæ.[2])

The preliminary experiments were performed on dogs, cats, and human volunteers; the individual's own blood was drawn off into sodium citrate solution, the corpuscles were centrifuged off, washed, combined with the metal, washed twice or three times until the supernatant fluid was free of metal, and then reintroduced intravenously in a saline suspension. In later experiments the blood of one animal was used for preparing the corpuscle-metal combination which was injected into another animal of the same species. In a subsequent series sheep or ox blood preparations were injected into dogs, cats, rabbits, and human beings and were found to produce the same effects as autogenous blood corpuscles. This, of course, made experimentation easier, as it was possible to keep a large stock in an ice-chest and perform a regular series of experiments with a constant preparation.

The animal experiments showed that it was possible to administer intravenously in this way doses of lead, copper, mercury, and other metals three to five times as great as would kill the animal if they were introduced intravenously in ordinary solution under the same conditions. Latterly I have been using lead and bismuth combined in this way for inoperable cancer, but it is too early yet to speak of results.

The ease of preparation, constancy of composition, and stability of the preparation, when properly taken care of, contrast with the difficulty of preparation and preservation of the ordinary solutions of colloidal lead as used at present by Blair Bell and others in cancer work.[3] Various metals and metallic substances have been used, including copper, lead, zinc, mercury, gold, silver, and iodine.

The phenomenon is probably a surface effect of the nature of adsorption, or a specific combination of the metal with some constituent of the envelope of the corpuscle. This is indicated by the fact that the corpuscles take up most of the metal when small quantities are used. Copper was used in these experiments as copper-sulphate solution, and as the dose was increased relatively more and more copper sulphate remained in the supernatant fluid. Similar results were obtained with cupric chloride and with a solution of cupric cyanide in potassium cyanide solution. Owing to the high toxicity of the latter drug, much smaller doses were given and the amount of cupric cyanide in the supernatant fluid was much diminished. After the second washing there was no metal in the supernatant fluid.

Where lead and bismuth were together combined with the corpuscles for the treatment of cancer it was found that the preparation contained: bismuth 4·8 per cent. and lead 2·7 per cent., both lead and bismuth being estimated as metal. It was possible to give a dose which contained 0·24 g. of bismuth and 0·135 g. of lead, but the usual dose was one containing 0·2 g. of bismuth and 0·11 g. of lead. It was repeated every three or four days until three or four doses had been given, and then an interval was allowed.

In the original experiments on cancer in 1924 copper was used. Although life was probably not prolonged, it was made endurable, and in some cases the patient put on weight for a while and ultimately died after only about two weeks' illness without any of the usual wasting. At present bismuth and lead combined are being tried, and it is hoped shortly to have a series on copper and lead combined.

I wish to thank Prof. W. A. Osborne for the use of his laboratories, and Prof. E. Hartung for having carried out the chemical analyses for me.

AN UNUSUAL CASE OF ACUTE INTESTINAL OBSTRUCTION.

By James Fanstone, M.D. Lond., D.T.M.,

and

Gerald Golden, M.B., B.S. Lond.

Fæcal impaction is mentioned in text-books of surgery as a cause of acute intestinal obstruction, but it is so rare at home that the description of the following case may be of interest. It is an extreme example of a disease which is quite common in the interior of Brazil—namely, an extraordinary sluggishness of the large bowel. An evacuation at intervals of ten days is considered no sufficient reason for seeking medical aid, while we have seen patients who have passed more than 40 days without action of the bowels.

The case is that of a married woman of 29, who was brought to us in September, 1926. She had not suffered from any serious illness previously, but for 12 years had complained of increasing irregularity of the bowels. Eighteen days before her arrival she had eaten enormous quantities of a fruit which resembles the grape, but has larger and harder stones. Since then she had had no action of the bowels, and had suffered much colicky abdominal pain.

On examination she was found to be five months pregnant with her first child. It was difficult to feel the uterus owing to the enormous abdominal distension, which was, however, most marked laterally. A huge fæcaloma occupied the entire descending and the left half of the transverse colon. Except at the proximal extremity, this mass was stony hard, and palpation caused much pain. A previous diagnosis had been made elsewhere of transverse presentation! It was impossible to feel the mass by rectal examination. There was no fever and the pulse-rate was 90. Two large enemas were administered but failed to produce either *fæces or flatus.*

A NOTE ON

MULTIPLE SUPERFICIAL ULCERS OF THE SMALL INTESTINE.

By K. KANAGARAYER, L.M.S. SINGAPORE,
D.T.M. BENGAL,
ASSISTANT BACTERIOLOGIST, INSTITUTE FOR MEDICAL RESEARCH,
KUALA LUMPUR, FEDERATED MALAY STATES.

AMONG ulcers of the small intestine, the single duodenal ulcer, the multiple typhoid ulcers of the ileum and lower alimentary tract, and tuberculous ulcerations have all been classified and descriptively labelled. In 3000 autopsies during the last four years I have found, in three cases, an ulceration of the small intestine which fails to conform to any of those three recognised types. As attention has been directed to a similar condition in a case reported by M. Scott and J. B. Cleland,[1] the post-mortem findings in these three cases are here briefly recorded.

Reports of Cases.

CASE 1.—On Jan. 26th, 1925, the body of a Tamil, said to have committed suicide by hanging, was brought to the District Hospital, Kuala Lumpur. Its condition suggested that a chronic wasting disease had driven him in desperation to take his life. At autopsy the only lesions were a series of superficial ulcerations in the small intestine extending from 1 inch from the duodeno-jejunal flexure to 4 feet from the ileocæcal junction. There were four or five ulcers in each foot of intestine, all running transversely, and the majority involving the entire circumference of the bowel. Some of them were quite narrow, others $\frac{1}{4}$–$\frac{3}{4}$ inch in diameter. The base was fairly smooth, and the edges only slightly raised. The peritoneal surface was not thickened in most cases, but a few showed slight puckering. In their distribution, serpiginous extension in the transverse axis of the bowel, and puckering of the peritoneal surface, they almost resembled tuberculous lesions, except that there was less puckering, edges and bases were less ragged, and tubercles on the peritoneal surface were absent. There was no evidence of tubercle in the abdomen or elsewhere. Smears made from scrapings of the bases and edges of ulcers, and of their peritoneal surface, showed no tubercle bacilli. Unfortunately, the ulcers were not histologically examined, but in view of the findings in the next two cases, it is probable that the histological picture would have been similar to that described below. A history of pain in abdomen and diarrhœa of four months' duration was obtained from the brother.

CASE 2.—On July 28th, 1927, a young male Tamil was admitted to the hospital with complaint of passing loose motions, five to seven times a day, without blood or mucus, for about a fortnight. He died on August 10th and autopsy revealed only nine small superficial ulcers in upper part of jejunum. A few ulcers were circular; but most of them were oval with their longer diameter in the transverse axis of bowel. The peritoneal surface of these ulcers was puckered. No protozoa or acid-fast bacilli were found in smears. Cultures yielded coliform organisms. The rest of the alimentary canal was normal, and no evident cause of death other than the ulcers was noted. The body was emaciated, and it is likely that the illness was of longer duration than indicated by the history. Sections of the ulcers showed chronic inflammatory changes with loss of the mucous and submucous coats.

CASE 3.—A Tamil, aged 30, was admitted to the hospital on June 19th, 1927, suffering from chronic urethritis, and progressive emaciation and diarrhœa. The Wassermann reaction was negative. Intestinal tuberculosis was suspected. He died on August 20th, and autopsy revealed transverse ulcerations along the whole length of the small intestine extending from the lower third of the duodenum to 2 feet from the ileocæcal junction, with four to five ulcers in each foot of intestine. The description already given to those in Case 1 applies equally to these. Sections showed no histological evidence of tuberculous condition. There was loss of mucous and submucous coats and evidence of chronic inflammation.

These three cases present an unusual type of ulceration of the small intestine. The ulcers were superficial and showed a tendency to healing and scarring. No explanation of the genesis of these ulcers can at present be given. So rare is the condition that a diagnosis antemortem must be extremely difficult. Radiographic examination of the small intestine might help in diagnosis. The anatomical resemblance to tuberculous lesion suggests that the ulceration extends transversely round the gut by following the course of lymphatics and blood-vessels; but the lymphoid nodules do not appear to be involved, as they are in typhoid and tuberculous ulcers.

DONATIONS AND BEQUESTS.—Sir Henry James Hall, Gloverswood, Charlwood, Surrey, left £1000 to St. Dunstan's Hospital for Blinded Sailors and Soldiers, and £500 to the London Association for the Blind.—Mr. Frank Sussum, of Cambridge, left £1000 to Addenbrooke's Hospital, Cambridge.—Mr. Ramsay Paxton, of Sunderland, left £700 each to Sunderland Infirmary and Sunderland Orphan Asylum.—Among other bequests Mr. F. L. Heyn, J.P., of Craigavad, County Down, left £1000 to the Royal Victoria Hospital, Belfast, to name two beds, one to be called the "Frederick L. Heyn and Helen B. Heyn Bed," and the other the "F. L. Heyn Head Line of Steamers Bed"; £250 to the Belfast Maternity Hospital; £250 to the Society for Providing Nurses for the Sick Poor of Belfast; £200 each to the Samaritan Hospital, Belfast, and the Ulster Hospital for Women and Children, Belfast.—Under the will of Sir Edwin Evans, J.P., of Battersea, the Bolingbroke Hospital, Wandsworth Common, S.W., will receive £1000 for general purposes and the Battersea General Hospital and the Royal Blind Pension Society of the United Kingdom £250 each.—Mr. Samuel Kidd, of Derby-road, Farnworth, near Widnes, left £1000 each to the School for the Blind, Hardman-street, Liverpool, the Royal Infirmary, Liverpool, the Eye and Ear Infirmary, Liverpool, and the Ethel Gossage Home, Farnworth Branch.—Mr. Matthew Turbitt, of Birkdale, Southport, left £1000 stock to the Southport Infirmary and, subject to a life interest, £1000 each to the Imperial Cancer Research Fund, Dr. Barnardo's Homes, the Church Army, the National Lifeboat Institution, and the North of England Children's Sanatorium at Southport. After other bequests the ultimate residue of the property will be divided between St. Dunstan's Hostel for the Blind, King George's Fund for Sailors, the Society for the Prevention of Cruelty to Children, the Royal Association in Aid of the Deaf and Dumb, the Southport and District Deaf and Dumb Mission, and the Southport and Birkdale Provident Society.

Reviews and Notices of Books.

SIMPLE GOITRES.

By R. McCARRISON, C.I.E., M.D., D.Sc., LL.D., F.R.C.P., Associate Fellow de l'Académie de Médecine, Paris; Lieut.-Colonel, I.M.S.; Pasteur Institute, Coonor, S. India. London: Baillière, Tindall and Cox. 1928. Pp. 106. 15s.

THE subject matter of a report by Colonel McCarrison to the International Conference on Goitre held at Berne in August, 1927, has been published in the form of a monograph and has been amplified by an introduction. A series of 143 excellent illustrations follow the report, and, if studied in the order in which they are arranged, tell their own story of the genesis of simple goitres. Three types are discussed: the adeno-parenchymatous or chronic hypertrophic goitre, the diffuse colloid type, and the lymphadenoid type. The similarity of these three goitres is confined to the thyroid swelling which is manifest in them all, even as the exanthemata have in common only the pyrexia which is their most prominent symptom. The adeno-parenchymatous and diffuse colloid goitres are endemic types and differ in their epidemiology, ætiology, and pathology; both may occur sporadically. Adeno-parenchymatous goitre occurs in mountainous regions, the diffuse colloid goitre in lowland regions and at or near the sea coast. Their geographical limits may overlap and they may occur together in the same locality. The first-named type is considered to be a true hypertrophy with the thyroid constantly straining to satisfy the needs of the tissues for its active principles but just falling short of doing so. Sufferers generally show evidence of hypothyroidism. This is essentially a place disease, and from time immemorial has been associated in its origin with water-supply. Two theories as to its causation have survived from amongst many promulgated, the iodine deficiency theory and the infectious or toxic theory. Colonel McCarrison is of the opinion that the truth may lie in a blend of the two, but it is rather difficult to see how such different conceptions could be made to overlap.

We have little precise knowledge as to the geographical distribution, epidemiology, ætiology, and biochemistry of diffuse colloid goitre. Its cause is probably to be sought in factors which interrupt the normal cycle of the thyroid gland's activity at the stage of colloid storage. It is most prevalent in children round about the age of puberty, and it progresses with remissions for from three to five years and then regresses. Iodine may play some part in its production, but is not the only factor involved. Thyroxin given by the mouth may have no effect, but the same drug administered intravenously rarely fails to cure the condition. The lymphadenoid type of goitre is not endemic. It is a hypertrophic reaction of a physiologically insufficient organ, with which is associated a preponderance of lymphocytic aggregates and fibrosis in the gland. It can be produced experimentally in rats by dietetic deficiency. McCarrison considers that the basal factor in the causation of this type of goitre in man also is a diet deficient in vitamins of the A, B, and C classes. This, however, has still to be proved. He considers that it is not related to iodine deficiency since the addition of iodine to the food neither prevents nor cures it.

This monograph will be of considerable value to those interested in thyroid disease, especially in that it directs attention to the importance of toxic and dietetic factors in the genesis of these conditions. It should also do something to counteract the modern tendency to the indiscriminate use of iodine in the prophylaxis and treatment of all forms of simple goitre.

THE SPECIES PROBLEM.

By G. C. ROBSON. Edinburgh: Oliver and Boyd. 1928. Pp. 283. 15s.

THE Keeper of the Mollusca at the British Museum has written an interesting and suggestive book. The first part discusses the criteria on which "species" of animals and plants may be separated from one another and represents well the modern point of view that habits, food, and such physiological characters must be taken into account equally with morphological structure. A species is a species not so much because it has a unique anatomy, but because it occupies a unique niche in its relations to the rest of animate nature. The second, and larger part, discusses the evolutionary divergence of species, and explores the various suggestions which have been made in the light of all the knowledge which has accumulated since Darwin. It is stimulating and provocative and reaches no conclusions. There is a useful bibliography and a poor index.

ENDOCRINOLOGY.

Internal Secretions and Metabolism in Infancy and Childhood. By FRITZ B. TALBOT, A.B., M.D., Clinical Professor of Pediatrics, Harvard Medical School. Supervising editor: R. S. HAYNES, Ph.B., M.D., Clinical Professor of Diseases of Children, College of Physicians and Surgeons (Columbia University), N.Y. London and New York: D. Appleton and Co. 1928. Pp. 178. 16s.

THIS is the thirteenth volume of a series of monographs on clinical pediatrics which are written primarily for the general practitioner. Both the authors are men of great experience in this subject and the work is authoritative. The purpose of the volume is to outline in simple terms those fundamental principles of metabolism which form the basis of modern clinical medicine. Twenty years ago most students were taught that medical therapy was based principally upon clinical observations, bacteriology, and post-mortem examinations. They learnt in great detail the symptoms and signs of the various diseases of nutrition and the lesions which were characteristically produced by each disease, but they knew very little about the abnormal physiology associated with the different syndromes. In the last two decades, however, physiologists and chemists have so increased our knowledge of the normal and abnormal functions of the body that our conception of disease has been greatly modified. The authors of this monograph have considered the subject from the most modern standpoint and have included an account of recent experimental work. The work is divided into five chapters. In the first of these the fundamental metabolic processes of childhood are fully discussed, and much useful information is given about the normal variations both of metabolism and growth which serve as standards of comparison in the following sections. In the second chapter pathological variations in metabolism are dealt with: a clear account is given of acidosis and alkalosis. An outline of ductless gland dystrophies is set out in the third chapter, only such data being included as have a definite experimental basis. The fourth chapter gives a description of the deficiency diseases of childhood, notably rickets and scurvy, while the fifth is devoted to such abnormalities of growth and development as infantilism, mongolism, and obesity. Many useful hints as to the treatment of these various conditions are incorporated. An excellent series of diagrams and photographs will be useful in helping the practitioner in differential diagnosis: the X ray photographs illustrating the various bone diseases are particularly good. The monograph can be cordially recommended.

Hormone und Inner Sekretion. By Dr. FRITZ LAQUER, Privatdozent an der Universitat Frankfurt A.M. Dresden und Leipzig: Verlag von Theodor Steinkopff. 1928. Pp. 136. M.8.50.

THE rapidity with which masses of facts and observations accumulate in the literature of internal secretions makes it difficult for one observer to follow even a limited aspect of the subject. Any attempt to verify all the results of the enormous number of workers in this field is out of the question, and each worker can only try to correlate his own findings with those of *well-accredited laboratories*. Dr. Laquer has gathered together much of the literature of hormones and internal secretions which has grown during the last 12 years; over 1200 references have been collected. He makes little effort to supply a critical survey: in the matter of physiological explanations of the actions of different hormones the reader is at liberty to choose whatever theory pleases him most without much guidance. With regard to clinical data, however, the results obtained by serious workers of different nationalities are substantially the same. The active hormones produce effects which vary only in degree in the hands of different observers. When physiologists and biochemists attempt to explain the modus operandi of the hormones the most diverse opinions are offered, and fundamental disagreement still exists.

Dr. Laquer does not attempt to resolve these differences, and his book will be of value to the research worker in that the literature is clearly summarised and references are given to articles in the less well-known special journals which may have escaped attention.

The Great Problem and the Evidence for its Solution.

By George Lindsay Johnson, M.A., B.C., M.D., F.R.C.S., F.R.P.S., F.R.S. Italy. With a Foreword by Sir A. Conan Doyle. London: Hutchison and Co. 1928. Pp. 380. 18s.

Public interest in spiritualism—a general name for the phenomena whose study constitutes "the great problem" attacked by Mr. George Lindsay Johnson—is reflected in the lay press and in a profuse literature which sometimes appears associated with the name or under the imprimatur of persons whose qualifications should give authority to their opinions. The object of Mr. Johnson's work, which has received the euology of Sir Arthur Conan Doyle, is "to collect all the evidence at our command, and to endeavour to convince the reader of the existence of a future life." The first part of the proposition is fulfilled by the collection and collation of a vast assortment of dreams and stories of apparitions, examples of clairvoyance and telepathy, spirit vocalisations and photography, and automatic writing; past and present beliefs and traditions being put under contribution, we have an index of proper names occupying more than 800 lines. In a chapter headed "Evidence of a future life from the miracles of the Bible, together with modern phenomena of a similar nature," many unusual cases of recovery from illness are given, but it is difficult to understand how the occurrence of healing, apparently brought about by mental processes, can be used as evidence of survival in any partly materialised form, and it is doubtful whether anyone, unless he is already a confirmed believer in spirit interference, will be impressed by the reasoning. Endeavouring to explain certain difficulties of the non-believer in spiritualism the author replies to his question, ". . . Why is it that everybody cannot get into touch with their friends on the other side?" by saying that "The reason is quite simple. In order to receive messages from the spirit world it is essential that a psychic or medium be present"; here, again, none but the converted will be satisfied with the answer. As an example of painstaking research in collecting stories of the "marvellous" the book is interesting, while at the same time it exhibits the kind of proof on which belief in so-called survival is based.

Even if the phenomena of the séance room, and the stories of supernormal occurrences be accepted, it does not follow that they are to be explained by spiritualistic agency, while there can be no denial that the belief in the sequence has opened the door to deception, sometimes of the most gross kind. It is necessary to glance only at the advertisements of some of the publications connected with the spiritualistic movement to realise this. In juxtaposition with announcements of services in "*temples*," "sanctuaries," and "churches," we have announcements from palmists, astrologists, and fortune-tellers, seductively brought before the public eye, while the vendors of unknown powers of diagnosis, of cures for consumption and cancer, of "female corrective herbs," of electric treatments, and galvanic belts, find a large public through these media, to judge by the amount of space which some of the advertisers are able to afford. Such being the associations of spiritualism as shown by its recognised press, the answer is supplied to the frequently reiterated complaint by spiritualists that their cult is ignored or ridiculed by science.

Clinical Diagnosis by Laboratory Methods.

Sixth edition. By James Campbell Todd, Ph.B., M.D., Professor of Clinical Pathology, University of Colorado School of Medicine; and Arthur Hawley Sanford, A.M., M.D., Professor of Clinical Pathology, University of Minnesota. London and Philadelphia: W. B. Saunders Company. 1927. Pp. 748. 28s.

"Todd" has long been known in this country, and "Todd and Sanford" is assured of an equal popularity. This is a book which is of particular value to the student, for the number and the excellence of the illustrations, the clarity of the language, and the short, but concise, notes on the indications for the applications of various tests and the interpretation of the results. The present edition has been brought thoroughly up to date, and all new procedures of clinical pathology as deserving admission, such as the Kahn test, the technique of duodenal intubation, and the tests of liver function, find place in its pages. Altogether, an excellent book.

Micro-Methods.

Mikromethodik. Quantitative Bestimmung der Harn-, Blut- und Organbestandteile in kleinen Mengen für klinische und experimentelle Zwecke. By Ludwig Pincussen, Direktor der biochemischen Abteilung des Städt. Krankenhauses am Urban in Berlin. Leipzig: Georg Thieme. 1928. Pp. 200. M.6.

This book, which now appears in its fourth edition, has been enlarged and improved. Opening with sections on general principles on the use of the colorimeter and on nephelometric methods, the author proceeds to give full experimental details for the determination of the constituents of urine and blood by approved micro-methods, many of which have been elaborated or improved by himself. In addition there are sections devoted to the estimation of the ash constituents of fæces or of tissues, and to the gasometric examination of blood by means of a modified Barcroft method. The book is clearly written and forms a handy compendium of micro-methods, suitable for clinical or experimental purposes, which can be carried out without the acquisition of elaborate apparatus or the use of a micro-balance.

To-day and To-morrow.

Metanthropos, or the Body of the Future. By Ronald Campbell Macfie, M.A., M.B., C.M., LL.D. London: Kegan Paul, Trench, Trübner and Co., Ltd. New York: E. P. Dutton and Co. 1928. Pp. 96. 2*s.* 6*d.*

Dr. Campbell Macfie adds a volume to the well-known To-day and To-morrow Series which should certainly be read by a large public, for the number of persons now intelligently interested both in anthropology and physiology is very large. We may conceive that the last and most important chapter of this little book will irritate many of these, and some of the general deductions may be challenged, but despite the drastic commentary upon one side of society contained in the following passage, the author's message is cheerful. "If love," he writes, "in the sense of strong physical and spiritual attraction between a man and a woman, have even temporarily weakened; if men no longer are drawn to women by their health—by their full breasts, and luxuriant hair, and well-formed limbs, and red lips, and fresh complexions, and feminine psychology—if nowadays women are so camouflaged with paint and powder and so attenuated by the decrees of fashion that there is little possibility of distinguishing the healthy and wholesome from the unhealthy and unwholesome—if men have grown so accustomed to paint and powder as to lose the love of the healthy and fresh—if sexual selection is no longer eugenic and no longer a matter of deep personal affinity—if men and women through modern dances and plays become sexually blasés—if the best men and women marry late and have small families—if religion and morality are out of fashion—if these things are so and in so far as they are so, the race is suffering and must suffer for perhaps more than one generation." These Juvenalia epitomise much which the author has to say, but none the less he comes to the conclusion that the majority of men and women are not yet touched by decadence and that the Anglo-Saxon stock with its mixture of Nordic and Celtic blood is so stable and so good that there is no fear of any lasting deterioration.

PHYSIOLOGY AND MEDICINE.

Pathological Physiology of Internal Diseases: Functional Pathology. Fourth edition (revised). By A. W. HEWLETT, M.D., B.S. late Professor of Medicine, Stanford Medical School. London and New York: D. Appleton and Co. 1928. Pp. 787. 35s.

THE advances in recent years of experimental physiology and particularly of mammalian physiology have thrown new light on the causation of disease and furnished new lines of treatment. Moreover, physiology has brought new methods of diagnosis to the clinical laboratory. The benefit has not been wholly one-sided, but attempts to correlate medicine and physiology in text-books have for the most part dwelt on the debt of medicine to physiology. This work is no exception. It was originally written by the late Dr. A. W. Hewlett, who began his medical career as a physiologist, later becoming a professor of clinical medicine, and it has recently received extensive revision, as a mark of appreciation to the author by ten of his medical colleagues. The book, in its present form, makes a special appeal to clinicians. Historical references are scanty, but a generous bibliography is supplied. Certain of the views on immunity here set out are already superseded, at least in this country, in favour of physico-chemical hypotheses, but, in general, the book may be accepted as quite up to date.

Précis de Physiologie. Seventh edition. By MAURICE ARTHUS, Professor of Physiology at the University of Lausanne. Paris: Masson et Cie. 1928. Pp. 1152. Fr.70.

A TEXT-BOOK of a thousand pages is not the prevailing notion of a précis, but evidently the bulk of this volume has not deterred medical students from buying it, since it has attained a seventh edition. The work differs in three respects from text-books of similar size in our language. It is more narrowly confined to the exposition of function, the author expressly avoiding the discussion of physiology from the point of view of physics and chemistry. Experimental technique is not described; for example, "tambours" appear in diagrams where "piston recorders" would be used in this country. Lastly, when results of recent researches are still controversial, these are omitted; these omissions may save the student's time but, we believe, only at the expense of loss of stimulation. More prominence is given to the medical standpoint than is usual in our text-books; thus, body temperature—a subject of great clinical importance—is fully discussed. A useful chapter is included on anæsthesia. British readers will find much of interest in this book.

THE PRINCIPLES OF INFANT NUTRITION.

By K. H. TALLERMAN, M.D., M.R.C.P., and C. K. J. HAMILTON, B.M., M.R.C.P. London: William Heinemann, Ltd. 1928. Pp. 183. 10s.

THE object of this book is to discuss the principles underlying infant nutrition, and to point out their application to the practice of infant feeding rather than to advocate any particular method. The authors have succeeded in giving a readable presentation of the physiology and biochemistry of nutrition in infancy. The relative advantages of various methods of feeding are discussed with impartiality, but the authors' interpretation of physiological theories disposes them to give preference to simple modifications of milk with added carbohydrate and low fat-content. Whole milk feeding is discouraged; percentage feeding is regarded as unnecessary. The reason for these judgments, which are probably in accord with the views of the majority of authorities in this country, are clearly explained. The authors are opposed to the use of citrate and of alkalis in general, and are convinced of the advantages of acid milks. The book is of convenient size, and each chapter contains a useful list of references. It may be recommended for the use of senior students and of practitioners who wish to obtain a concise account of modern teaching.

PSYCHE MINIATURES.

A Symposium of Culture. By G. ELLIOT SMITH, D.Sc., Professor of Anatomy in the University of London; BRONISLAW MALINOWSKI, D.Sc., Professor of Anthropology in the University of London; HERBERT J. SPINDEN, Ph.D., Peabody Museum, Harvard University; and A. GOLDENWEISER, Ph.D. Pp. 89.

The Alchemy of Light and Colour. By OLIVER L. REISER, Assistant Professor of Philosophy in the University of Pittsburg. Pp. 86.

Intelligence and Mental Growth. By CLAUDE A. CLAREMONT, B.Sc. Lond. Pp. 138.

The Standardisation of Error. By VILHJMUR STEFANSSON, M.A., LL.D. Pp. 110.

London: Kegan Paul, Trench, Trübner and Co., Ltd. 1928. 2s. 6d. each.

As will be seen from the above titles a large range of knowledge is covered in these four little books of the Psyche Miniature Series, and it is given in so brief a form that further condensation as a review is impossible. The Symposium of Culture, for example, may be regarded as the abstract of a review of its own subject from four different angles of view, a lucid preamble by Prof. Elliot Smith setting out the controversial points in respect of the diffusion of social knowledge. Prof. Reiser, in discussing the phenomenon of colour, shows how the ingenuity of the scientist in overcoming limitations has brought about the position that no one *can predict* what the future may hold in store. Starting with the difficulties which have always presented themselves to the ordinary observer confronted with the differing views which the psychologist may hold in respect of colour as an attribute, or as an element in consciousness, he discusses the chemical and biochemical bases of colour and closes with a section, not at all easy to follow, in which he attempts to bring out the nature of the interdependence between consciousness and chemistry. Mr. Claremont's little book makes far simpler reading, partly because a well-written preamble prepares us for the chapters which follow, and partly because he has a real gift for illustrating his thesis by simple analogies. The chapter on intelligence and instinct forms a good example of his ability to state in clear language exactly what he means, and no one can read it without acquiring a valuable lesson in what may be termed psychological grammar.

Dr. Stefansson is gay; the following sentences with which the second part of his little book commences gives a good idea of his respect or disrespect for the discernment of the public. "The most striking contradiction of our civilisation is the fundamental reverence for truth which we profess and the thorough-going disregard for it which we practise. . . . God and truth have from the earliest times been the two ideas that have commanded the greatest reverence' . . . philosophers have discussed at great length whether God is good, they have never discussed whether truth is good." Whereupon the author starts to ask if there be any sound reason why truth should be exempted from that fundamental scrutiny to which even the gods have had to submit. It is, of course, obvious that the same question may be asked of the same people and receive entirely different replies, each of which may be true, the variants being due to the fact that the answers have been given in accordance with the varying implications contained in the question, although not put into words. On this ground, by itself, we may agree with the author that, like religion, truth is neither good nor bad; but the examples which he adduces in order to come to the conclusion make very agreeable reading.

MEDICAL AND ALLIED TOPICS IN LATIN POETRY.

By HENRICH OPPENHEIMER, D.Lit., LL.D., Ph.D. Lond., M.D. Heidelberg, M.R.C.P. Lond., Barrister-at-Law. London: John Bale, Sons and Danielsson. 1928. Pp. 445.

IN a sad little preface Dr. Oppenheimer gives as the origin of this book a certain enforced leisure which fell upon him during the period of the war owing to his unlucky position as an enemy alien—in his own words "an innocent victim of social and '*horribile dictu*' to some extent of professional ostracism." Accordingly, the author sought and found comfort in the company of the classical writers, and the result is an interesting collection of passages, contained in some 20 well-known Latin poets, all being relevant to medical knowledge. These passages he has arranged according to their subject matter, providing explanatory notes and English translations, some of which are quite familiar. Where the versions are metrical he gives the correct attributions, but with regard to both English and Latin texts he admits occasionally having taken certain liberties, when a variant reading seemed to bring out better the significance of a passage; as the exact alterations made are not indicated this seems rather a daring proceeding. As might be expected, the majority of the quotations come from well-known authors of the last century B.C. and the first 60 years of the Christian era, a period which includes Lucretius, Virgil, Ovid, Horace, Catullus, Martial, and Juvenal—the quotations from the last four being extremely numerous. The two older playwrights, Plautus and Terence, are also freely drawn upon, and all the passages extracted from this wide range of reading are arranged under a subject-index, so that citations having reference to medicine, surgery, and obstetrics are grouped together, while separate sections are devoted to various special diseases, to biology and physiology generally, to sociology, materia medica and toxicology, neurology, insanity, and dietetics. The result is a really interesting book, which although in no sense a medical history, none the less throws a remarkable light upon the medical practice and medical superstitions of the past, especially upon those of imperial Rome. An interesting little chapter, entitled the Medical Register of Poets, gives an alphabetical list of the physicians who are mentioned by name in the works of the various authors consulted, and by this register we are reminded how frequently was the medical profession the object of Martial's biting criticisms.

JOURNALS.

ACTA PÆDIATRICA. Vol. VII., 1928.—Supplement 2 comprises the proceedings of the Fourth Scandinavian Pædiatric Congress. Prof. S. Monrad reviews the subject of congenital pyloric stenosis from his experience of 223 cases. He holds that the essential defect is a congenital hypertrophy and that this is not secondary to spasm. He has found medical treatment as efficacious as surgical.—Dr. H. von Willebrand favours operative treatment of pylorospasm in all but the mildest cases.—Dr. L. Kena-Apajalahti gives an account of the histological appearances of the brain of a cretin child. These were of the nature of an agenesis rather than a failure of subsequent development, and corresponded closely to what is found in simple primary amentia. He suggests that the cerebral defect in cretinism is primary, i.e., an accompaniment rather than a result of athyroidism.—Prof. A. Yllpö discusses the relative merits of carbohydrate and protein feeding in the treatment of infantile intoxications, and expresses his decided preference for the latter.—In a paper by Dr. O. Utter attention is drawn to the frequency with which an alimentary saccharosuria, in the absence of glycosuria, occurs in infants. The increasing tendency to use cane sugar in the artificial feeding of infants gives added importance to this occurrence. He summarises the results of his investigations on the various factors (concentration, alkalinity, and fat content of the feeds) which seem to influence the excretion of saccharose.—Dr. A. Lichtenstein discusses the ætiology of scarlet fever, and the immunity of the new-born to this infection. He considers that the evidence afforded by this immunity is compatible with the view that scarlet fever is a manifestation of anaphylaxis.—Prof. E. Bloch describes the clinical features of a series of cases of cœliac disease. He was unable to find in them any evidence of avitaminosis. Two of his cases showed typical tetany; ultra-violet irradiation cured the latter but aggravated the intestinal disturbance. He suggests that in this disease tetany may be the result of fixation of calcium by the soaps formed in the stools.—Dr. C. Friderichsen gives an account of a series of cases in which intractable and fairly localised muscular pains occurred, with some degree of paresis. Some of the cases were children in the third year, and in them the symptoms gave rise to suspicion of muscular "growing pains." In all of them there eventually appeared some evidence, clear or equivocal, of a scorbutic condition. Taken in conjunction with the histological changes found by Höjer in experimental scurvy in guinea-pigs, he suggests that these observations yield evidence of a "pre-scorbutic myopathy," which may be present in a latent stage of scurvy and may simulate subacute rheumatism.—Dr. Knut Wejdling discussed some of the factors in the pathogenesis of spasmophilia. He thinks that the most important one is the electrostatic condition of the tissues, and believes that estimation of the potassium content of the blood is of greater value than the calcium content.

Supplement 3 consists of a monograph by Dr. C. W. Herlitz on the regulation of the blood-sugar in healthy infants and in those who exhibit signs of the exudative diathesis, particularly of eczema. Series of experiments are described and their interpretation is discussed at length. Among other conclusions reached are the following. In infants with fresh cutaneous eruptions of less than two weeks' duration the fasting blood-sugar value was higher than in normal infants or in those with long-standing eruptions; the alimentary blood-sugar curve reached a higher maximum but its return to the normal was not delayed. The increase in tone of the vegetative system—particularly in the liver—which is associated with the alteration in carbohydrate metabolism he regards as the result, and not the cause, of the cutaneous eruption.

THE LANCET.

ONDON: SATURDAY, JULY 7, 1928.

LOCAL GOVERNMENT REFORM.

changes, affecting the health services of local rities throughout the country, flow from the als in this year's budget for revising the ice of rates upon agriculture and industry. s easily realised that the Chancellor of the quer could not exempt agricultural land and ltural buildings from rates and could not grant e relief to industrial hereditaments without ting from the national finances some com- ion for the loss of rating power which the local ities would feel. But it could hardly have so readily foreseen that the revision of the al relations between the Exchequer and the thorities would involve the decision to transfer ovisionally proposed in 1926) all poor-law ns to the county councils and county boroughs. as, of course, been long admitted that the poor-law unions, set up in 1834 under a based on the local market towns and the xisting means of access thereto, have ceased m the ideal arrangement—at any rate, for l purposes. As the Government's white (Cmd. 3134) points out, at present every rural n the country has institutions which, with the in the number of persons institutionally d in rural areas, are seldom kept full. Their es for medical treatment cannot economically dernised. Meanwhile other local authorities been established which are charged with the oth of preventing disease and of treating the Between the functions of these newer authorities ose of the poor-law guardians there is over- g. If and when the poor-law is transferred he guardians to the county and county borough ils, there will be a chance to eliminate this pping, to make a better classification of the and to provide more economically the institu- l facilities for which the demand is progressively sing. In its application to London the new means the abolition of the Metropolitan m Board and the transfer to the London County cil of the services which the Board at present tains. The cost of poor relief being spread over County of London through, the county rate, etropolitan Common Poor Fund (the cause of uch political controversy and the object of so improvisation in recent years) will also be hed.

ong the existing Exchequer grants which the plan will discontinue all over the country are percentage grants in aid of health services— or tuberculosis, maternity and child welfare, e of the blind, venereal diseases, and mental ncy. When local authorities no longer receive grants, a new annual grant in aid of revenue e substituted for the first quinquennial period. ormulæ of ascertainment and apportionment tricate and will require careful examination ose who possess the necessary actuarial qualifi- s. In broad outline the Government plan l help the poorest areas which, under the per- e grant system, could least afford to maintain lequate standard and yet received the least assistance from national funds. Thus the rating relief, which the Government claims to be giving to productive industry by this year's budget, is found to be merely one step in big changes in the machinery and finance of local government. The programme appears to be far-sighted and shows evidence of a logical coördination which has not always been a feature of changes in English administration.

AN

◆

THE CONTROL OF DIPHTHERIA.

When Behring made his famous experiments on passive immunity he was lucky enough to choose one of the few organisms which arouse great antitoxic powers in the blood of inoculated animals. His results in the treatment of diphtheria were therefore remarkable—so remarkable as to encourage a hope that all bacterial infections would meet their match in the new curative sera. Certainly there seemed no doubt that diphtheria was conquered, since by effective treatment of every case the spread of the disease must necessarily be checked. But with the passing years these hopes have not been realised, and the revolution in therapeutic measures has by no means abolished the necessity of using them. The incidence of diphtheria not only remains high, but, in London, has for many years been steadily rising, whilst the case-mortality has shown an alarming increase in Germany and other countries where serum treatment has long been employed as a routine. Much of this failure is, of course, due to delays before the remedy is administered, but as medical men have been taught for a generation that early treatment is essential, and the public has been informed incessantly of the need for early diagnosis, little immediate improvement can be expected in this direction. We cannot avoid the conclusion that current methods will not further reduce the mortality among serious cases, and that merely curative measures are not going to control the incidence of the disease by themselves.

Both in the United States of America and in Germany the greater prevalence of diphtheria has been associated with unusual malignancy. The symptoms include glandular enlargement and periglandular œdema with foul-smelling faucial deposits and discharge from the nose and throat, and there is commonly severe toxæmia, cardiac paralysis, renal failure, and early death. Fatalities, it is recorded, have occurred despite administration of antitoxin even within the first 24 hours, and this absence of the usual response to treatment has sometimes suggested that the clinical condition was dominated by a secondary streptococcal infection. Successes have been reported from the combined use of antidiphtheritic and antistreptococcal serum, but its efficacy as a routine measure is still in dispute. Although we in this country have enjoyed relative freedom from severe infections of the kind, experience of the malignant form has been recorded in certain towns; in Bristol, for example, Dr. D. S. Davies, the late medical officer of health, reported that the years 1919 to 1926 were characterised by an increase in the severity of the disease. Dr. H. S. Banks, of the Leicester Isolation Hospital, says that in the past two years diphtheria has taken on a more malignant form than he has ever previously encountered, and this has led him to explore the possibilities of more intensive treatment. As he and Dr. George McCracken record, in a paper published elsewhere in this issue, their cases were divided into groups according to severity, and the 27 regarded as "malignant," having severe adenitis, were treated with very large amounts of antitoxin. One had as much as 140,000 units in one dose, and the average quantity given was 71,000 units of antitoxin intravenously, with 31,000 units by intramuscular injection. Fifty-two cases whose infection was not quite so severe were given, on the average, 19,000 units by each route, whilst the remaining 214, of only moderate severity, had an ordinary intramuscular dose of 8000 to 16,000 units. The details of technique are set out in their communication and need not be considered further here; it is enough to say that the advantage claimed for the intravenous route is the rapidity with which maximal concentration of serum in the circulation is obtained, contrasting with a delay of 24 hours with intramuscular and three days with subcutaneous injection. BANKS and MCCRACKEN rightly describe toxic diphtheria as an acute emergency, and consider that to give a "haphazard subcutaneous injection of serum" is equivalent to postponing operation on a gangrenous appendix for three days. The total doses, which rose to 200,000 units in some cases, are not, of course, unprecedented. V. BIE, of Copenhagen, is quoted as having used as much as 300,000 units in very grave cases. They are, however, far greater than those in general use by the profession, or previously employed at the hospital, where it is noteworthy that the case-mortality has been reduced from 9·3 per cent. in the preceding decennium to 2·6 per cent. in the year ending last March. Excluding patients who died within 24 hours of admission, and those with laryngeal diphtheria, it was only 1·7 per cent., which is much the same as the death-rate of 1·3 per cent. in a series of 1456 cases treated last year by BIE. It is further stated that the incidence of complications, notably paralysis, has also diminished, and these results are so remarkable that they must lead to reconsideration of the current view that it is useless to give antidiphtheritic serum in doses of more than 30,000 to 50,000 units.

More successful use of antitoxin would not be likely, however, to make much difference to the incidence of the disease, and the question arises whether the best use is being made of the prophylactic methods at our disposal. The answer is in the negative. In this country the progress of toxoid-antitoxin immunisation, though steady, is slow, first because the profession has apparently not been convinced that the method is effective and, secondly, because the public is suspicious of inoculations and disturbed by the disasters of Vienna and Bundaberg. Last year's increase of diphtheria in New York, where immunisation has been tried on a large scale, may lead to disparagement of the method, and it is certainly disappointing. But it must be remembered that the city has a population of 1½ million children under the age of 15, only about a third of whom have been immunised; the remaining unprotected million, —mainly children of pre-school age—offer an abundance of material susceptible to attack during a period of increased prevalence. In Germany the Prussian Health Council has recommended widespread prophylactic inoculation among children in districts with a high incidence of diphtheria, and in Berlin immunisation is being provided free for all children between the ages of one and six years. We are glad to learn that more and more local authorities in this country are offering similar facilities. Thus, at Manchester, the City Council has just approved a scheme by which for six months toxoid-antitoxin will be issued gratis to practitioners and health officers, and immunisation will be recommended to the public through every possible avenue. Information is to be offered at maternity and child welfare centres, at the various children's hospitals, and by way of the school medical service, as is being done in some of the London boroughs, 12 of which now provide means of protection by toxoid-antitoxin inoculation. It is regrettable that schemes of this kind are not being tried more widely, if only on economic grounds; for the sum of £30, which is what a diphtheritic child costs London, would protect 200 children against the disease. The safety of the procedure is actually thrown into relief by the two or three disasters that have occurred abroad, for they would not have been possible with the immunising preparations obtainable from reputable sources in this country. As Dr. VEITCH CLARK told the Manchester City Council, we have the evidence of many large fever hospitals that diphtheria among the nursing staff has been stamped out by the immunisation of nurses before their exposure to diphtheria in the wards, and no accidents following immunisation have been reported in Great Britain. The method may not be infallible but it is certainly safe, and, to quote the London County Council's health committee, "According to authoritative American observers, as a result of observation over periods ranging from three to six years, no child who received the full immunising course, and had given a Schick-negative reaction, subsequently contracted diphtheria." The profession in this country may wish for evidence from sources nearer home, but such evidence on a large scale can scarcely be available until the method is given wider use. The case in its favour is already so good that parents ought to be given a chance of protecting their children if they are willing to do so. Not least ought this opportunity to be given in London and other large cities, where the incidence and mortality of diphtheria are high.

CONCURRENT EVOLUTION.

THERE has been a revival of the public interest in the problems of evolution, particularly in so far as they affect our conception of man's origin. Evidence of this interest is to be found in a recent number of the *Outlook* (June 23rd), where Mr. JAMES STANLEY LITTLE discusses the problem of human origin under the title of "concurrent evolution." Mr. STANLEY LITTLE is an evolutionist, but is of opinion that the theory now accepted by the majority of anthropologists —namely, that all existing races of mankind, white, yellow, and black, are the descendants of a common "Adam," or ancestor, is "false and unscientific." He believes that just as two men may discover the same idea or make the same invention independently, so two new and very similar species or breeds of animals may come into existence separately in the wide womb of nature. The underlying idea, that of parallel evolution or orthogenesis, is one which has been, and is being, much debated by professional students. The late Prof. KLAATSCH put forward the idea, which had been tentatively held by some of the older anthropologists, that peoples of the Mongolian type came of an orang ancestry, while the peoples of Africa came of another anthropoid lineage. Some 16 years ago Prof. WOOD JONES startled his fellow anatomists by putting forward the theory that man and the anthropoid apes had arisen and evolved independently from a basal primate stock, acquiring their many points of structural resemblances in the course of their separate evolution. Quite recently Dr. H. FAIRFIELD OSBORN, who has made a special study of the evolution of horses and elephants, and proved amongst them instances of parallel or "convergent" evolution, has separated man's lineage from that of anthropoid apes and carried both as independent lines into a distant geological past, thereby exciting much current comment throughout the American continent. Even Huxley wrote in a letter to Romanes (1888) that "it is quite conceivable that every species tends to produce varieties of a limited number and kind, and that the effect of Natural Selection is to favour the development of some of these while it opposes the development of others along their *predetermined* line of modification." Thus in postulating an independent origin and an almost predestined evolution for the diverse races of modern humanity Mr. Stanley Little can claim a considerable amount of professional justification. The point at issue is not the truth of evolution; that theory is accepted by all intelligent critics; what has yet to be finally determined is the mode by which new breeds or species are produced in a state of nature. The laws of heredity are not in doubt, but their degrees of plasticity have still to be probed.

Mr. Stanley Little carries his inquiries into the realm of culture and is a candid critic of those who hold that high civilisations of a similar kind must stand to each other as daughter to mother. For example, he is severe on those who seek to trace the old civilisations of Central America to an Asiatic of Egyptian original. Here again Mr. Stanley Little has stepped unwittingly into another arena of hot professional debate. It was a youthful visit to Mexico that convinced the late Sir Edward B. Tylor that the ancient civilisation of that land must be sought for in the Old World, but as he went on he found so many points which were difficult of reconciliation that he relapsed to the older explanation which postulated that human mentality was the same all the world over and therefore solved the problems of a budding civilisation by adopting corresponding measures. In recent years Prof. Elliot Smith has brought forward much cogent evidence to demonstrate that Tylor's original idea was right—that there had been a cultural drift across the Pacific from Asia to America many centuries before the time of Columbus. At the present time the "diffusionist" theory—that a forward swing of the pendulum of evolution, whether in ideas, arts, or in biology, is single-centred—is in the ascendant; from a cradle of inception ideas and invention spread from land to land. A concrete instance may serve to illustrate the nature of this problem. So many are the points of difference—as well as of resemblance—between the railroad services of America and of England that did we not know as a historical fact that one was derived from the other we might be inclined to cite them as cases of independent or parallel evolution.

Mr. Stanley Little cites the development of languages in support of his contention that evolution works in a "concurrent" way. "All languages were," he asserts, "evolved innocent of literary form, yet they all, or nearly all, generated, so to speak, grammars of sorts, roughly considered, having affinities in their major aspects, however different in their minor details." Certainly it is true that no living thing—and language and art are just as alive as any form of protoplasm—can continue without change, slow as that change may be. Already we see that the English tongue of Britain and that of the United States do tend to move apart, whatever may be the nature of the driving force involved. But when we find languages such as Italian, Spanish, and French, with so many close resemblances, we should explain those resemblances by postulating a common ancestry—even if we knew nothing of Latin. We should never dream of ascribing them to independent or parallel origins. In like manner we are justified in ascribing all Aryan forms of speech to a mother tongue. The biologist in explaining the close resemblances between all living races of mankind proceeds in exactly the same manner. Why should he postulate several sources when one is sufficient? The student of human evolution brigades man and anthropoid apes together because they are so alike in the fundamentals of their structure. He does not postulate separate origins for them, because if evolution is true it is much easier to derive man's structure from that of a primitive anthropoid than from a very lowly ape-like tarsioid.

Annotations.

"Ne quid nimis."

TESTAMENTARY CAPACITY.

The plain man might think that, if a person be certified as insane, he is ipso facto incapable of formulating a sane will. This was the opinion of Lord Brougham, who held that the mind acts as a whole, and if there be insanity in any one part, then the whole is invalid. With the advance of psychiatry, the issue has been narrowed down to the question—"Was this man capable of making this particular will at the time of its execution?" In Banks *v.* Goodfellow, Lord Chief Justice Cockburn put the pertinent question, "But what if the mind, though possessing sufficient power, undisturbed by frenzy or delusion, to take into account all the considerations necessary to the proper making of a will, should be subject to some delusion, but such delusion neither exercise, nor be calculated to exercise, any influence on this particular disposition, and a rational and proper will is the result; ought we, in such a case, to deny to the testator the capacity of disposing of his property by will?" Thus the whole problem was once more thrown open, and solicitor and medical man must combine to determine whether the testator's mental condition is or is not such as should invalidate his will.

Mr. Noel Middleton has reviewed this position in a paper read before the Medico-Legal Society on June 28th. He reminded his audience that, to have testamentary capacity, a man must possess an understanding of the nature of the business on which he is engaged, a memory of the property of which he has to dispose, and of the persons who have a claim upon him, and must appreciate the manner in which he desires his property to devolve. Soundness of mind is not definable, and the law—fortunately for all of us—does not require a perfectly balanced mind, but lays stress upon the functions of memory and understanding. The disposing mind must have natural capacity not unduly impaired by age, enfeebled by illness, or tainted by any morbid influence. It is essential that no disorder of the mind shall poison the testator's natural affections, but it is immaterial if his judgment be perverted by spite, caprice, or frivolity. Where these affections pass into insanity is as difficult to determine, said Mr. Middleton, as the point at which twilight becomes darkness. The extremes, however, are easily recognisable. From the medical man the court wants to know if he has observed in the patient signs of disease of the brain from any cause, and, if so, whether that disease had any direct bearing on the terms of the contested will. Mr. Middleton classified insanity under four heads, which served his purpose, though they would not appeal to the modern psychiatrist: mania, melancholia, monomania, and dementia. Wills made in the "lucid interval" of mania have often been upheld, but no solicitor should draw up a will under such circumstances without medical advice, and proof would be required that power of rational thought had been restored. A diseased state of mind once having been established is presumed to continue. In Cartwright *v.* Cartwright it appeared that the strongest proof of the existence of a lucid interval arises from the act performed during the alleged interval. If that act were a rational act rationally performed without assistance, a lucid interval might be presumed. The principal danger with the melancholic patient is that, through sheer lack of interest in the world about him, he may consent to sign any document placed before him. Under the head "monomania" Mr. Middleton discussed the vexed question of eccentricity and delusions. Psychiatrists know well the amazing power some paranoid patients have of concealing their delusion when it is to their advantage to do so, and they have more than once defeated skilled cross-examination. Among the "dementias" come the very large and important senile group, and that most difficult of all patients from the testamentary point of view, the general paralytic. Again, as Sir Robert Armstrong-Jones pointed out in the discussion, there is epilepsy, "one of those dominating tyrannical conditions that affects the emotions perhaps more than any other disease."

The jury is faced with the problem of deciding whether or not the deceased was possessed of testamentary capacity. They look to the medical man for a clear and simple account of what he saw and heard when he interviewed the testator. They are happy if their medical witness can describe from notes made at the time his patient's bearing towards the relatives, his memory for recent and remote events, the nature of his delusions, his attitude towards previous wills and any changes made in the most recent of them, and his ability to enumerate, within reasonable limits, his possessions and his dependants. The medical man should always interview the patient alone, save for a nurse or colleague, and ought if possible to see the patient more than once, taking full notes of each interview. The more facts he can lay before the jury, the more likely are they to be able to come to a just decision.

BERI-BERI ON DIFFERENT DIETS.

IN the old conceptions of the ætiology of beri-beri, rice—and often spoiled rice—played the chief part. We know now that rice is not an indispensable factor, though it is a very frequent one. In No. 8 of the Indian Medical Research Memoirs, J. Taylor, C. de C. Martin, and U. Thant describe an interesting study of beri-beri among rice-eaters in Burma; while at a meeting of the Royal Society of Tropical Medicine and Hygiene, on May 17th last, Dr. G. W. Bray gave an account of infantile beri-beri on the Pacific island of Nauru, where the native population never touches rice, but subsists largely on coco-nut products.

Taylor and his co-workers examined the dietaries of a number of the different racial constituents of the population, and concluded that beri-beri is not an important disease among the native Burmese, but is almost confined to the large coastal towns, where it affects imported Indian coolies, not Mohammedans nor vegetarian Hindus to any extent, but chiefly the so-called meat-eating Hindus. It also occurs among Burmans in isolated forest camps, where conditions cause the food-supply to be severely restricted. The disease is shown to have a seasonal incidence, being most prevalent from August to February; it thus occurs chiefly in the wet period, setting in a couple of months after the onset of the monsoon. This greater prevalence in the wet season is tentatively correlated with the greater deterioration, at that time, of stored rice from damp and moulds. Where rice was used which was freshly pounded at frequent intervals, beri-beri did not occur, whereas in exactly corresponding communities, where long-stored rice was used, beri-beri broke out. It is not known whether the moulds introduce a toxic factor, or, as seems more likely, simply make such pericarp as remains on the rice more friable, so that it easily crumbles off and is lost, and with it the vitamin which it contains. It is interesting to see the factor of deterioration restored to its old important place in the ætiology.

The conditions in which beri-beri develops on the island of Nauru show contrasts with those prevailing in Burma. The disease occurs among a population which never touches rice: it affects only breast-fed infants, and its incidence is heaviest in the dry season. Its appearance in the island is only recent and is connected in an interesting way with the political history of the place. The island of Nauru is held by Australia, under mandate from the League of Nations. Supply of alcohol to native peoples in mandated territory is not allowed. In Nauru the intoxicating drink which the natives have used is made from the toddy palm, but now they are no longer supposed to make it. The toddy contains much yeast, and concentrated toddy yeast was found to cure the infants suffering from beri-beri. When a dietary is very limited, interference even with the source of alcohol may cause disaster. A similar instance occurred in the war, when a South African native labour battalion was brought to France; an alteration was made in the preparation of their fermented drink,, scurvy developed, and one of the recommendations made to combat it was the return to the usual native method of preparation.[1] The more frequent incidence of beri-beri in Nauru in the dry season is found to be correlated with a special factor, just as the correspondence of the disease with the wet season in Burma was found to be. In wet weather in Nauru the toddy palm yields much more of the fermentable sap from its inflorescence than it does in dry, and although the consumption of toddy by the natives has been much reduced under the mandate, it is not to be supposed that it would ever completely stop. Thus any factor tending to lower the production of this anti-beri-beri agent would operate to increase the number of cases. Among the interesting contributions to the discussion that followed Dr. Bray's communication was one by Dr. W. H. Aykroyd, who described beri-beri in Newfoundland, where the dietary consists chiefly of white bread and salt meat. He had noticed there that the majority of the cases, 80 per cent. of the whole, were males, and he believed that some social factor must operate to produce this result, but he did not yet know what it was.

SYPHILIS REFRACTORY TO TREATMENT.

THE term "malignant syphilis" is applied somewhat loosely to two distinct groups of cases—namely, those in which the eruption is severe and profuse, with or without profound constitutional symptoms, and those in which the manifestations are refractory to treatment, or recur during the actual administration of modern remedies. A case from the latter group, examples of which occur from time to time in every venereal clinic, is reported in the *Dermatologische Wochenscrift*, June 2nd, p. 727. A man, aged 42, received the usual arsenical and bismuth course for a profuse secondary eruption. Fourteen days later condylomatous lesions recurred on the tongue and round the anus, although the Wassermann reaction was negative. Renewed antiluetic treatment brought about the disappearance of the lesions and a positive W.R. The first mercurial injection of the third course was followed by an urticarial syphilitic eruption, and the W.R. became negative again. This eruption was uninfluenced by intensive treatment with neosalvarsan, bismuth, and iodides, but the W.R. remained negative. An intracutaneous injection was given of syphilitic vaccine from rabbit chancres ("luotestin," 0·2 c.cm.): pronounced local and focal reaction in the lesions followed the first injection, and after the second the W.R. became positive. The third injection resulted in the involution of the eruption. Four more doses of luotestin were given, and the treatment was then purposely stopped. Ten days later there was a gyrate macular rash on the trunk and syphilitic papules on the right tonsil, and now the W.R. was, as it should be, positive. Another injection of luotestin and a small dose (0·15 g.) of neosalvarsan promptly cleared up both these manifestations, which had not recurred at the time of reporting the case. It will be noted that an abnormally reacting organism, indicated by the urticarial eruption, negative W.R., and refractiveness to salvarsan, was converted into a normally reacting mechanism, as evidenced by the macular eruption, positive W.R., and receptivity to salvarsan. Rosner's view that the negative W.R. during the eruptive stage is a sign of defective natural protection is one which will be shared by most authorities, and it seems probable that the injections of luotestin to some extent stimulated production of antibodies. This would explain the appearance of local and focal reaction in the rash itself, but does not altogether account for the paradoxical gyrate eruption with tonsillar lesions that followed ten days after the seventh injection of luotestin. Rosner suggests the word "contra-reaction," and raises the question of an altered response of the blood-vessels in the lesions, leading to their paradoxical contraction, with dilatation of vessels in the vicinity. The theory is too conjectural for further consideration at present, but there is no doubt that administration of luotestin and similar protein bodies, which may or may not be specific, have a practical bearing on the treatment of salvarsan-refractory types.

THE CAUSE OF SUDDEN DEATH IN CRIMINAL ABORTION.

AN adequate explanation of sudden death during criminal attempts to procure abortion is still to seek: in medico-legal cases the cause has often been ascribed to shock, but this view has not met with general acceptance. Sudden fatalities are so rare in legitimate operations that they have never become associated in the minds of obstetricians with the therapeutic induction of abortion, the evacuation of an incomplete abortion, or the closely allied procedures of dilatation, exploration, and curetting of the uterus. Few even of those with a long and varied experience of hospital and special practice have met with a single case. To explain this apparent anomaly factors peculiar to the special circumstances in which criminal abortion is attempted have been invoked, such as mental distress, fear, and other emotional states in the patient, or haste, lack of skill, or faulty methods in carrying out the manipulation. The economic stress of the war and post-war years in Central Europe has greatly increased attempts to procure abortion, and the mortality accompanying it has drawn attention to the causes of death or of serious complications. In Germany the method commonly adopted is the injection under pressure of fluids, usually soapy water, into the uterus. According to H. von Hoesslin[1] this manipulation is not infrequently followed by sudden and dangerous symptoms, either cardiovascular or cerebral in origin, and a non-fatal case of the latter type is recorded and discussed in the light of others collected from German literature. As it is almost impossible to avoid the injection of air with the fluid, death is frequently ascribed to air embolism, and von Hoesslin's interpretation of his case in the absence of post-mortem investigation is that the quantity of air in the cerebral arteries was too small to cause serious circulatory disorder but was sufficient to interrupt temporarily the nutrition of the delicate cortex. The case he recorded was that of a woman of 26, who collapsed and later became unconscious after the injection into the uterus, at high pressure, of a soap solution. The patient was soon after admitted to the Hamburg-Eppendorf Hospital where she had several left-sided epileptiform convulsions, and on the day after admission expelled a dead fœtus. The urine was free from albumin and sugar, the Wassermann reaction was negative, and lumbar puncture gave no evidence of raised pressure. There were no further fits and consciousness began to return after the fourth day, though the patient had a right-sided paresis, remained drowsy, and complained of severe headache for some time longer. All symptoms gradually cleared up and she was discharged well in four weeks. The passage of blood containing air-bubbles through the pulmonary capillaries is shown to be possible by experimental work on animals. It has been stated, also, that in 30 per cent. of mankind the closure of the foramen ovale is imperfect to a degree sufficient to permit frothy blood to escape from the right to the left side of the heart. When death results from circulatory disturbance following the introduction of air into the vessels the cause would appear to be frothing of the blood on the right side of the heart; in less acute cases there may have been penetration into the coronary veins of chains of bubbles working against the current and the consequent production of cardiac failure. This sequence of events has been produced experimentally in animals by L. Jung and L. Auger.[2] The great importance of learning the real explanation of sudden death in criminal abortion makes it essential that every case of the kind should be carefully investigated, and the possibility of air-entry into the circulation is one that should be fully explored.

FRACTURES SET BY MACHINERY.

Dr. John J. Moorhead, of New York, describes[3] a method of reducing displacement in fractures of the long bones, which he considers superior to those now in use. Plaster-of-Paris cases are applied above and below the seat of fracture and traction and counter-traction are applied through them. The distal portion of plaster is connected with an electromotor which can be regulated so as to exert any amount of undulating force likely to be desirable. When the surgeon is satisfied that correction has been attained, the motor is stopped in the position of maximum pull and the gap between the plasters is filled in with more plaster-of-Paris. The apparatus is not fully described in the paper, nor are the illustrations of much help in elucidating the details of the mechanism, but we gather that the minimum desired degree of tension is produced by a hand screw, superimposed upon which is the alternating pull of the electromotor. The alternate pull and relaxation is produced by an eccentric. The apparatus is obviously not one for every practitioner to keep in his surgery, and is only likely to be used in casualty departments of hospitals which deal with a large number of fractures. Radiograms are reproduced from a case of compound fracture of both leg bones, treated by this method, but judging, as we must, by this one case, we feel no certainty that its results will be any better than those obtainable by less elaborate methods. It seems probable that traction will have to be maintained at its maximum for a good many hours while the fresh plaster is setting to a sufficient degree to resist compression, and that trouble is likely to arise from this pressure. The final radiogram does not show a perfect anatomical result, although functionally it may be perfect. A costly and elaborate apparatus such as this must justify its introduction by improved results after repeated tests if it is to gain a permanent place in the surgical armamentarium.

PERMANENT ENLARGEMENT OF A CONTRACTED PELVIS.

THE permanent enlargement of a contracted pelvis by means of bone-grafts has been effected in two cases by Dr. F. H. Albee.[4] The technique involves a horizontal incision of the symphysis pubis, section of the pubic ligaments, and separation of the innominate bones at the symphysis. A graft taken from the tibia is then inserted in the hiatus between the innominate bones, and is sutured in place with kangaroo tendons. The author explains that the graft method has the advantage over symphysiotomy and pubiotomy that these may have to be repeated at each pregnancy, while the enlargement of the pelvic ring by bone-graft is permanent. Another reason given by Dr. Albee for his preference is that, in his experience, the force required to separate the bones is very great, and he considers it undesirable that this force should be exerted wholly through the presenting part of the child as it must be after symphysiotomy. Presumably he is here considering the child, for it seems doubtful whether for the mother a sudden severe wrench would be any more desirable. Many surgeons, especially in America, believe that the sacro-iliac joints are liable to give rise to painful symptoms, even when so far as can be ascertained they have not been subjected to undue strain. A permanent wedge, for the insertion of which the bones have had to be separated 1½ inches, must surely cause tension of ligaments, if not some degree of displacement of these joints. It is recorded that both patients operated on were delivered of normal children after operation; one of them has since had three normal labours. We are not told, however, whether they are free from backache or other symptoms which might be expected to follow such a gross insult to the skeletal frame. Indeed, the case reports which form part of Dr. Albee's article are somewhat meagre, and though there was doubtless justification for drastic action, little evidence is submitted on this point. In one of the patients no trial labour seems to have been allowed, and the report of the obstetric history of the other, who had had a craniotomy, gives no details of the events leading up to a catastrophe which might have been due to causes other than a contracted pelvis. Obstetricians are constantly being asked to perform Cæsarean sections on patients who subsequently deliver themselves without interference, and it must be emphasised once again that convincing proof of the impossibility of normal delivery should be forthcoming before any operative procedures are contemplated.

CARDIAC PAIN IN RHEUMATIC FEVER.

It may be assumed that in acute rheumatic fever præcordial pain with hyperalgesia generally means involvement of the heart. The subject has now been studied statistically by Dr. H. F. Swift and Dr. C. F. Hitchcock,[1] who have investigated 154 cases of acute rheumatic fever over a period of more than seven years. They show that the frequency with which præcordial pain and hyperalgesia is encountered is roughly proportional to the intensity of the rheumatic infection, and hence to the frequency of cardiac involvement. While the absence of cardiac pain during the acute attack does not necessarily show that the heart has escaped injury, its presence is strong evidence of damage to the valves. Præcordial pain with hyperalgesia is observed more often during recurrent rheumatic fever than during the first attack. In the first attack of fever two-thirds of the patients with præcordial pain showed other evidence of cardiac involvement, and almost all the remainder developed cardiac lesions later, or during subsequent attacks. Incidentally, Swift and Hitchcock confirm the well-known observation that patients with subcutaneous rheumatic nodules almost always have concomitant signs of cardiac involvement. They point out that as our knowledge of the nerve-supply of the heart is still incomplete, any conclusions about the mechanism by which the pain arises must be mainly tentative. It may be noted, however, that the cardiac lesions of rheumatism are in the perivascular and adventitial tissues, and that the evidence goes to show that the cardiac tissues capable of giving rise to painful sensations are mainly situated in the epicardium, pericardium, and the adventitial coats of the aorta and coronary arteries, the endocardium and myocardium being probably insensitive. They think that the pain associated with pericarditis is not due to mechanical irritation by rubbing, but rather to the intensity and nature of the underlying inflammatory process. A pericardial rub may often be heard in patients who have no pain, and an extensive pericarditis may be discovered at the autopsy of a patient who has never had præcordial pain. On the other hand, severe pain may be felt before clinical evidence of pericarditis is manifest. Signs of rheumatic pericarditis are almost always accompanied by evidence of valvular and myocardial involvement, but valvulitis and myocarditis of equal severity may occur without pericarditis, and in these cases similar præcordial pain is often present. "It seems, therefore," they say, "that the præcordial symptoms which have been described and attributed to pericarditis by many observers are merely indicative of the severity of the pancarditis."

THE PROVISION OF GLASSES FOR VERY FINE WORK.

Eyestrain among persons performing very fine work is presumably due partly to excess of accommodation required, partly to excess of convergence. An investigation just carried out by the Industrial Fatigue Research Board[1] concerns two sets of workers, the one engaged in the mounting of lamp filaments, the other in a process of threading for the loom in which a thread has to be drawn through as many as 123 eyes per inch. The mounting of lamp filaments was the finer work and for this purpose glasses were provided which added 4 dioptres of accommodation for each eye and 6 degrees converging prisms for work at about 6 inches. At the same time any error of refraction was corrected. The result was an increase of output, though this was slight among those who were previously the best workers. To loom workers the relief given was 2 dioptres of accommodation and 4 degrees converging prisms in addition to the distance correction. Here also the result was favourable, and Mr. T. G. Clegg, who prescribed the glasses, attributes the improvement chiefly to the relief afforded by the convex prisms. The objection is obvious that this wholesale treatment does not sufficiently take into account individual requirements. The need for relief might well be present at the age of 30 when the average accommodation is about 8 dioptres and absent at the age of 20 when it is about 11 dioptres. The power of convergence again is one that varies greatly in different individuals not only with age but with general health and, of course, with muscle balance. Fatigue is liable to ensue, according to Landolt, if more than one-third of the converging power (reckoned in metre-angles) is continuously called upon. Among those workers whose refraction is not normal the wearing of glasses with distance correction would by itself do much to diminish fatigue. But psychological factors, especially the influence of suggestion, cannot be ignored when the results are being assessed, while the incidence of physical fatigue from causes not primarily connected with the eyes has also to be considered. The outcome of this study is that the provision of glasses relieving both accommodation and convergence for very close work has, on the average, a beneficial effect, but to what extent the efficiency of any particular worker may be enhanced by their use cannot be judged without detailed investigation.

THE SHEFFIELD MEDICAL SCHOOL.

The celebrations to be held next week at Sheffield in connexion with the centenary of the medical school, now the medical faculty of the University of Sheffield, recall to all who would learn of the development of medicine in this country a very interesting page in history. The story has been well told by the late William Smith Porter, senior physician to the Sheffield Royal Infirmary, whose delightful essay on the subject has just been published, and deserves to be widely read. This story commences in July, 1828, but previous to this date a Sheffield surgeon, Mr. Hall Overend, had begun to make collections for a museum of anatomy, human and comparative, the use of which by his apprentices and those of his neighbours was providing a quite unusually good scientific training to Sheffield students. The museum was the private property of Hall Overend and his son, Wilson Overend, but when, in 1828, a movement was promoted by a Sheffield physician, Sir Arnold Knight, and others for the establishment of a medical school in the city, it was proposed to utilise the Overend Museum. This was sheltered in a wing of the Overends' house, and when this building was contemplated as the nucleus of the new school the troubles that arose from the proposal to employ private property for public purposes were inevitable. For one group of medical men, out of a recognition, no doubt, of the Overends' pioneer labours, desired to maintain the Overend Museum as a permanent centre of the new school, while another group, foreseeing the complications that might ensue, wished to make a new start, taking the form of a Medical Institution. The term "school" was not employed in connexion with this later movement, which was directed rather to the formation of what would now be considered a learned society, and this perhaps accounts for the fact that in the first instance the Overends, father and son, appear to have been quite friendly to the scheme. But the new Medical Institution soon became the centre of medical education in Sheffield, in accordance with the prevailing views for the training of students, and thus for a short time Sheffield possessed two rival schools, with the disagreeable division of opinion thus implied. But the dissension came to an end dramatically by the disappearance of the Overend Museum. The Museum itself had been removed from the back of the Overends' house, owing to the feeling that pathological specimens were inconvenient property to have on domestic premises at a time when the public feeling against body-snatching was so high. And the action was certainly prudent, for in 1835 the Museum was sacked and destroyed by a mob, inflamed by the accounts of the Burke and Hare atrocities. But although the Sheffield School of Medicine did not have its material start in the Overends' Museum, Dr. Porter says, and all will agree with him, that Hall Overend was the true founder of the Sheffield medical school. The rise of an entirely independent institution was the only sound method to ensure permanency for the ideals of the Sheffield citizen, but the ideals themselves were implanted by Hall Overend.

---

[1] Jour. Amer. Med. Assoc., March 3rd, p. 678.

[1] On the Relief of Eyestrain among Persons performing Very Fine Work. By H. C. Weston, M.J.Inst.E., and S. Adams, M.Sc. Industrial Fatigue Research Board Report No. 49. H.M. Stationery Office. 1928. 1s. 3d.

While the beginnings of the Sheffield School of Medicine are quite clearly chronicled, the next stage appears to have escaped public notice generally, for even the Sheffield Local Registers are silent as regards the school between the years 1835 and 1850. Evidently the school showed no promise of great developments before the year 1883. But in that year the association with the Firth College wrought a magical difference in outlook and performance, and four years later the foundation-stone of the new school in Leopold-street was laid, after which the record of success becomes progressive. Of the growth from a university college to a faculty of medicine in a university nothing need be said, as such recent medical history must be familiar to all our readers. We follow Dr. Porter in quoting the concluding words of the inaugural address at the foundation of the Sheffield School of Medicine in 1828. "If it be competent," said Sir Arnold Knight, "to supply that knowledge which the increasing wants of an improving profession so urgently require—if it be calculated to advance the interests of the general practitioner—if by increasing the intelligence it add to the dignity of the profession and render its honours still more an object of ambition among the truly great—if by promoting professional skill it tend to alleviate the sufferings of mankind . . . then will the Sheffield Medical Institution succeed: and it will succeed—because it will deserve success." No doubt these words were greeted one hundred years ago with an approval that their powers of prophecy deserved.

A DINNER TO SIR ROBERT JONES.

ON Thursday, June 28th, a group of surgeons—friends, colleagues, and pupils—entertained Sir Robert Jones to dinner at the Café Royal, London. A book, specially written for the occasion and entitled The Robert Jones Birthday Volume, was presented to him, comprising a collection of surgical essays written by experts in his own subject with full knowledge of the position occupied by Robert Jones. This feeling was admirably set out by Sir Berkeley Moynihan, who was in the chair, in a speech distinguished alike by its brilliance and its affectionate intimacy. As an indication of the feelings which prompted the tribute, a few of Sir Berkeley's actual words may be quoted:—

> "This volume, written by a band of brothers, is dedicated with greatest respect and with warmest affection to Sir Robert Jones on the occasion of the seventieth anniversary of his birth. The opportunity to pay tribute to our friend, in whom we recognise one of the masters of surgery, was most eagerly welcomed. We felt that it gave us the chance to say openly what has long been in our hearts, in regard to his work for our profession, and in acknowledgment of the inspiration, encouragement, and example he has given to all who have had the high privilege of association with him. All those who contribute to this volume are proud to think that the influence of Robert Jones, of his methods, and of his teaching has inspired them, has found a place in their work to be transmitted by them in due time to their successors. Spirit alone is immortal. In the practice of orthopædic surgery the spirit of Robert Jones will live for ever. To Robert Jones, great surgeon, inspiring teacher, loyal colleague, and good friend, we affectionately inscribe this volume."

In addition to Sir Robert's daughter and son-in-law, Mr. and Mrs. Frederick Watson, and his son and daughter-in-law, Mr. and Mrs. Arthur Probyn Jones, the following were present: Sir Berkeley Moynihan, Sir Harold Stiles, Sir John Lynn-Thomas, Mr. E. Muirhead Little, Prof. Murk Jansen, Mr. A. B. Mitchell, Dr. Thurstan Holland, Sir William de Courcy Wheeler, Mr. E. Laming Evans, Mr. H. A. T. Fairbank, Prof. E. W. Hey Groves, Mr. R. C. Elmslie, Mr. A. S. Blundell Bankart, Mr. W. Rowley Bristow, Mr. Naughton Dunn, Mr. G. R. Girdlestone, Mr. Harry Platt, Mr. D. McCrae Aitken, Mr. W. H. Trethowan, and Mr. T. P. McMurray.

INTERNATIONAL STANDARDISATION OF DIGITALIS AND ERGOT.

THE first insight obtained by any student into the principle of international units of measurement dates from his school days. When he opened his first text-book on physics he learned with surprise that the metre, which was the familiar basis of many of his sums, could be defined with accuracy only as the distance, at the temperature of melting ice, between two marks cut in a bar of durable metal preserved in Paris. It would be absurd to pretend that such precise standards will ever be available in the sphere of pharmacology or therapeutics, but their development on scientific lines must depend largely on the extent to which it is possible to set up units of measurement common to all countries. The practitioner has hitherto not been very exacting in his demands for standardised drugs, or, indeed, very receptive to suggestions from pharmacologists that a popular mixture is not necessarily a potent one. He has been content to assume that the preparations of such drugs as digitalis, squill, and ergot in common use are of uniform strength without inquiring closely into the grounds for this assumption. Recent research has shown that his confidence is misplaced, and that the great variations in clinical response which he has doubtless attributed to the idiosyncrasies of the patients are at least as likely to be due to the differences in the activity of the drug exhibited. The Health Organisation of the League of Nations is thus doing most valuable work by collecting together experts from all countries with the idea of devising tests for the potency of those therapeutic substances which cannot be standardised by purely chemical means. The permanent Commission appointed by the League to consider the standardisation of sera, serological reactions, and biological products have already dealt with salvarsan, insulin, and pituitary extract on these lines, and the report[1] of their last session, held at Frankfort in April last, shows that they have made considerable progress towards the establishment of a uniform international unit for preparations of digitalis

---

[1] Publications of the League of Nations: Health, 1928, iii., 6.

The late Prof. Rudolf Magnus of Utrecht was asked in 1925 to make a dried powdered *preparation* of the leaves of *digitalis purpurea* of a certain strength. He was instructed to use for this purpose a mixture of 10 different powders, made from leaves properly dried at 55–60° C., to adjust its activity by biological assay on cats, and to distribute the *preparation* for international use. The activity of the standard *product was to* be controlled by annual tests, and if it should deteriorate, or the supply become exhausted, a new preparation of equal activity was to be made. This *work* was duly carried out, and favourable reports on the standard product have been received from various countries. The Commission of the League of Nations have therefore decided definitely to adopt the preparation for international use. *Arrangements* for renewal of the standard have had to be reconsidered owing to the death of Prof. Magnus, and Dr. Bijlsma, of Utrecht, has been entrusted with the task. Only when the new standard has been proved by various biological tests—such as intravenous infusion in mammals or the lethal dose method in frogs—to be identical in activity with the existing one, will it be forwarded to the National Institute for Medical Research for distribution on behalf of the League of Nations. In future, when the dosage of digitalis or its preparations is expressed in units of activity, the unit employed will be the specific activity contained in 0·1 g. of the international standard powder. As to ergot, in view of the results of recent clinical work,[2] showing that the essential factor in the activity of ergot on the uterus is the action of the specific alkaloids, the Commission have decided to proceed with the standardisation of ergot and its preparations by a method measuring its content of the specific alkaloid (ergotoxine or ergotamine). For this purpose the method of Broom and Clark, using the isolated uterus of the rabbit, will be adopted. The possibilities of preparing a stable standard for squill are now being explored. When such popular drugs as digitalis, ergot and squill have been added to the list of standardised substances, some important obstacles to the correlation of clinical impressions with experimental observations will have been removed.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointment has been notified:—Surg. Comdr. G. H. Hayes to *Barham*.

ROYAL ARMY MEDICAL CORPS.

Col. F. J. Brakenridge, late R.A.M.C., retires on retd. pay on reaching the age for retirement.

Lt.-Col. T. E. Fielding, from R.A.M.C., to be Col., vice Col. F. J. Brakenridge.

Maj. J. P. Lynch to be Lt.-Col., vice Lt.-Col. T. E. Fielding.

Capt. T. S. Law to be Maj.

ARMY DENTAL CORPS.

The undermentioned Lts. (on prob.) to be confirmed in their rank: R. G. J. Tovey, A. K. Inglis, W. McD. Birse, W. P. Baxendine, and N. I. Macmillan.

TERRITORIAL ARMY.

Capts. R. B. Lilly and I. J. Williams to be Majs.

2nd Lt. H. R. Vernon (late R.F.A.) to be Lt.

H. A. Eccles, L. D. Williams, and J. Wright to be Lts.

General Hospitals: Maj. J. Wallace, from Gen. List, to be Lt.-Col. and to comd. the 13th (4th Lond.) Gen. Hosp., vice Lt.-Col. (*Bt. Col.*) A. H. Gosse, vacated.

ROYAL AIR FORCE.

Flying Officer J. Hill is promoted to the rank of Flight Lieutenant.

INDIAN MEDICAL SERVICE.

The undermentioned officers retire: Lt.-Col. A. Murphy and Maj. A. Seddon (on account of ill-health).

---

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXXIII.

THE SURGICAL TREATMENT OF CHRONIC INFECTIONS OF THE SEMINAL VESICLES.

CHRONIC infections of the seminal vesicles are responsible for a considerable amount of ill-health, causing as they do persistent urethritis with unfitness for marriage, sterility, crippling arthritis, myositis, relapsing cystitis with rigors, epididymitis, and many other complications of "subinfection" or "intermittent bacteriæmia." Local urethral treatment, diathermy, vesicular massage, intravenous injections of neosalvarsan, or protein shock therapy will often bring about a cure. But many cases remain where cure can be hastened or can only be attained by lavage of one or both seminal vesicles by way of the vas. The operation of vasostomy or vasotomy, devised by Belfield,[1] of Chicago, in 1905, since modified by him and others in many important particulars, and performed by him on more than 1100 patients, should be more widely known and practised in this country, since recent improvements in technique have done away with complications which at first proved troublesome and caused the operation to be viewed with disfavour.

The operation has been criticised chiefly on the ground that if it is not properly carried out it may *lead to a stricture of the vas* with consequent sterility. Quite apart from the fact that most of the patients who need the operation are already sterile as the result of the disease of the vesicle, it is now known that stricture of the vas should not follow the operation when performed according *to* the latest *technique*; and, indeed, it is likely to render fertile many persons who without it would be condemned to permanent sterility. It appears, from numerous observations and experiments, that colloid silver, or other chemical, when *injected* into the lumen of the seminal tract does not injure in any way the epithelial lining of that tract. On the other hand, if colloid silver or other chemical be permitted to leak into the interstitial tissues around the vas, funiculitis may be produced, *and in some cases* lead to a stricture of the vas at the site of the incision. Such a condition can be remedied by the perfected operation of vasectomy with end-to-end suture. But with the new technique of vasotomy this necessity is not likely to arise. For instance, Dr. Clinton Smith, of Kansas City, reported 100 consecutive cases in which he was able to test the sperm at long intervals *after* the operation. In 98 of the cases living sperm was found. The chances, then, of sterility seem remote.

All who have had extensive experience of this operation are now pretty well agreed that attempts to leave a *cannula* in the vas *for* repeated washings should be given up. It was these attempts that led to reflux of the chemical injected and to subsequent stricture formation. It was found that stricture might result whatever chemical antiseptic was used for the injection. It was *not* the nature of the antiseptic, but it was the reflux of the antiseptic into the interstitial tissues that caused *the stricture*. Since colloid silver is found in practice to be the most efficient antiseptic, it should be used in preference to *any other* so far suggested, such as acriflavine.

The operation should not be carried out in the out-patient department. Patients should be confined to bed for two or three days at least, preferably four to five days.

Technique of Vasotomy.

The operation can be carried out under local or general anæsthesia. If *a local* anæsthetic is preferred, it is administered as follows. Pick up the cord at the top of the scrotum and inject into its substance 5 c.cm. of 1 per cent. novocaine adrenalin solution. Choose the site of the skin incision near the top of the scrotum and inject along this with a fine needle some 10 c.cm. of ½ per cent. novocaine adrenalin solution.

---

[1] Jour. Amer. Med. Assoc., 1905, xliv., 1277.

The vas should be isolated beneath the scrotal skin with the gloved fingers or a special clamp and a small incision be made directly down until the coverings of the vas are exposed. The vas is caught by a pair of sharp-toothed Volkman's forceps and held up in the left hand. With a few touches with a sharp knife the outer coatings of the vas are cleared until the flat handle of a scapel can be gently insinuated between the vas and the other structures of the cord. This is thrust through so as to keep the vas well out of the wound, after which any bleeding points that need attention should be securely ligatured. The vas must be well cleared of the surrounding tissue sheaths, an important point. With a fine-pointed tenotone a tiny opening is now made in a longitudinal direction through the wall of the vas so as to expose the lumen. This can soon be learnt by practice and is the most delicate part of the operation. A fine stiff length of silkworm-gut is now threaded into the vas and will usually pass easily for some 10 in. towards the vesicle. In some cases inflammatory strictures of the vas or inspissated pus will prevent the passage of this gut, in which case it may be thought advisable to desist from injecting the vas. If the lumen is patent a thin sling of gauze is inserted under the handle of the scapel to steady it and catch any drops of escaping fluid. A blunted needle (gauge 20) attached to a well-fitting syringe filled with 10 c.cm. of 5 per cent. colloid silver is insinuated into the lumen of the vas, great care being taken not to rub up the mucous membrane with the point of the syringe. Those who have had little practice are advised to inject sterile water to see if the passage is clear before resorting to the main injection. Five c.cm. of 5 per cent. colloid silver are then slowly injected and should flow easily away to fill the vesicle and ampulla. If 5 c.cm. flow in quite easily, a further 5 c.cm. may be injected. After a pause the syringe is removed and the opening in the vas most carefully closed with one or two 00 catgut sutures. These sutures should only take up the outer coat of the vas and should effectually prevent all reflux of the chemical injected. The vas is then dropped back into place and the skin united with a catgut stitch.

The patient should be confined to bed for at least three or four days to prevent complications, as a little fever is not unusual. The colloid silver may not appear in the urine for many days after the injection. In such cases the effect is always curative. Cures of the infected vesicle will be obtained in the majority of the cases by one injection. If a cure is not attained, then the vas can be exposed a second time a week or ten days later, and the injection repeated at a site a little higher up. In this way risk of stricture and sterility is avoided and the desired result is obtained.

Indications for the Operation.

The agreed indications for the operation are as follows: In all cases of non-tuberculous seminal vesiculitis without intense perivesiculitis refractory to non-surgical treatment due to the gonococcus, colon bacillus, streptococcus, and other pyogenic bacteria: (*a*) causing a chronic urethral discharge; (*b*) aspermia or necrospermia with sterility; (*c*) bacteruria and rigors; (*d*) arthritis or myositis; (*e*) attacks of recurrent epididymitis; (*f*) chronic cystitis following prostatectomy.

The diagnosis is established especially by careful rectal palpation of the vesicles with the trained and expert finger, the presence of necrospermia and pus in a condom specimen of the sperm, persistent relapsing swellings of the epididymis, and bacteriological investigations of the spermatic fluid. Experience can alone decide as to whether the operation must be carried out on one or both sides in any particular case. It is not always necessary to operate on both sides.

Vasotomy in Gonorrhœa.

Recently vasotomy has been advocated for all cases of acute gonorrhœa. I have been so impressed by the immediate and rapid cure of cases of chronic vesiculitis where no other treatment has been employed, except a single lavage of one or both vesicles, that I am quite prepared to believe that lavage of the vesicles on one or two occasions might rapidly cure recent acute gonorrhœa. Kenneth Walker's experiments on animals and certain clinical features of urethritis are suggestive in this connexion. The results of experience can alone decide such a question. The operation of vasotomy has come to stay. It must remain an operation to be practised only by those who are willing to give up some time to learning accurately the technique, and should not be condemned by those who have had no experience of it or who refuse to follow the minute steps necessary for success. I have had many striking results with it in a series of extremely difficult cases.[2] I cannot too strongly call for its consideration by those who are in charge of venereal disease clinics and military and naval hospitals.

Consulting Surgeon to St. Paul's Hospital.

PRESENTATION TO MR. WHITE WALLIS.

WITH 4700 members and a progressive Council the Royal Sanitary Institute has established itself as an organisation which has an important place in the community. Every year it arranges some 250 meetings and lectures in various parts of the country; it conducts examinations for health visitors, and organises those which qualify sanitary inspectors; it annually distributes 60,000 copies of a journal reaching a high standard of public interest; it keeps up a valuable museum visited by large numbers of people; and it has rendered excellent service in arousing interest in sanitary science throughout the Empire, branches having been established in most of the Overseas Dominions. While this steady development has been the work of many hands, it is largely due to the assiduous and capable service of the permanent staff, of which Mr. E. White Wallis, O.B.E., the secretary and director, has been the principal member for 48 years. Mr. Wallis has shown himself a skilful organiser, equipped with imagination and foresight. His gifts have been applied unceasingly to the work which he undertook in 1880, and his success as a manager must be evident to all who have attended the congresses of the Institute or studied its history. At the dinner at the Café Royal, given in his honour on June 27th, the Duke of Northumberland, President of the Institute, was unfortunately prevented from taking the chair as he intended, but Prof. Bostock Hill, who took his place, clearly expressed the feeling of the company when he said that Mr. Wallis's services, both in quantity and quality, must be almost unrivalled. After a presentation had been made, Mr. Wallis referred to the widespread activities of the Institute, which had now, he said, attained a standing which would form a foundation for future work and development. In this development we hope that he will continue to take an active share.

AMERICAN BEDS AT THE ROYAL FREE HOSPITAL.—Last week Mr. Horace Lea Washington, United States Consul-General, presented the endowment and name-plate of the "Martha Washington" bed for which £1000 has been given by the American Women's Club. At the same time Lady Hewart presented a cheque for £400 for the endowment of a "Louisa Mary Alcott" crib.

The late Prof. Rudolf Magnus of Utrecht was asked in 1925 to make a dried powdered preparation of the leaves of *digitalis purpurea* of a certain strength. He was instructed to use for this purpose a mixture of 10 different powders, made from leaves properly dried at 55–60° C., to adjust its activity by biological assay on cats, and to distribute the preparation for international use. The activity of the standard product was to be controlled by annual tests, and if it should deteriorate, or the supply become exhausted, a new preparation of equal activity was to be made. This work was duly carried out, and favourable reports on the standard product have been received from various countries. The Commission of the League of Nations have therefore decided definitely to adopt the preparation for international use. Arrangements for renewal of the standard have had to be reconsidered owing to the death of Prof. Magnus, and Dr. Bijlsma, of Utrecht, has been entrusted with the task. Only when the new standard has been proved by various biological tests—such as intravenous infusion in mammals or the lethal dose method in frogs—to be identical in activity with the existing one, will it be forwarded to the National Institute for Medical Research for distribution on behalf of the League of Nations. In future, when the dosage of digitalis or its preparations is expressed in units of activity, the unit employed will be the specific activity contained in 0·1 g. of the international standard powder. As to ergot, in view of the results of recent clinical work,[2] showing that the essential factor in the activity of ergot on the uterus is the action of the specific alkaloids, the Commission have decided to proceed with the standardisation of ergot and its preparations by a method measuring its content of the specific alkaloid (ergotoxine or ergotamine). For this purpose the method of Broom and Clark, using the isolated uterus of the rabbit, will be adopted. The possibilities of preparing a stable standard for squill are now being explored. When such popular drugs as digitalis, ergot and squill have been added to the list of standardised substances, some important obstacles to the correlation of clinical impressions with experimental observations will have been removed.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointment has been notified:—Surg. Comdr. G. H. Hayes to *Barham*.

ROYAL ARMY MEDICAL CORPS.

Col. F. J. Brakenridge, late R.A.M.C., retires on retd. pay on reaching the age for retirement.

Lt.-Col. T. E. Fielding, from R.A.M.C., to be Col., vice Col. F. J. Brakenridge.

Maj. J. P. Lynch to be Lt.-Col., vice Lt.-Col. T. E. Fielding.

Capt. T. S. Law to be Maj.

ARMY DENTAL CORPS.

The undermentioned Lts. (on prob.) to be confirmed in their rank: R. G. J. Tovey, A. K. Inglis, W. McD. Birse, W. P. Baxendine, and N. I. Macmillan.

TERRITORIAL ARMY.

Capts. R. B. Lilly and I. J. Williams to be Majs.

2nd Lt. H. R. Vernon (late R.F.A.) to be Lt.

H. A. Eccles, L. D. Williams, and J. Wright to be Lts.

General Hospitals: Maj. J. Wallace, from Gen. List, to be Lt.-Col. and to comd. the 13th (4th Lond.) Gen. Hosp., vice Lt.-Col. (Bt. Col.) A. H. Gosse, vacated.

ROYAL AIR FORCE.

Flying Officer J. Hill is promoted to the rank of Flight Lieutenant.

INDIAN MEDICAL SERVICE.

The undermentioned officers retire: Lt.-Col. A. Murphy and Maj. A. Seddon (on account of ill-health).

---

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXXIII.

THE SURGICAL TREATMENT OF CHRONIC INFECTIONS OF THE SEMINAL VESICLES.

CHRONIC infections of the seminal vesicles are responsible for a considerable amount of ill-health, causing as they do persistent urethritis with unfitness for marriage, sterility, crippling arthritis, myositis, relapsing cystitis with rigors, epididymitis, and many other complications of "subinfection" or "intermittent bacteriæmia." Local urethral treatment, diathermy, vesicular massage, intravenous injections of neosalvarsan, or protein shock therapy will often bring about a cure. But many cases remain where cure can be hastened or can only be attained by lavage of one or both seminal vesicles by way of the vas. The operation of vasostomy or vasotomy, devised by Belfield,[1] of Chicago, in 1905, since modified by him and others in many important particulars, and performed by him on more than 1100 patients, should be more widely known and practised in this country, since recent improvements in technique have done away with complications which at first proved troublesome and caused the operation to be viewed with disfavour.

The operation has been criticised chiefly on the ground that if it is not properly carried out it may lead to a stricture of the vas with consequent sterility. Quite apart from the fact that most of the patients who need the operation are already sterile as the result of the disease of the vesicle, it is now known that stricture of the vas should not follow the operation when performed according to the latest technique; and, indeed, it is likely to render fertile many persons who without it would be condemned to permanent sterility. It appears, from numerous observations and experiments, that colloid silver, or other chemical, when injected into the lumen of the seminal tract does not injure in any way the epithelial lining of that tract. On the other hand, if colloid silver or other chemical be permitted to leak into the interstitial tissues around the vas, funiculitis may be produced, and in some cases lead to a stricture of the vas at the site of the incision. Such a condition can be remedied by the perfected operation of vasectomy with end-to-end suture. But with the new technique of vasotomy this necessity is not likely to arise. For instance, Dr. Clinton Smith, of Kansas City, reported 100 consecutive cases in which he was able to test the sperm at long intervals after the operation. In 98 of the cases living sperm was found. The chances, then, of sterility seem remote.

All who have had extensive experience of this operation are now pretty well agreed that attempts to leave a cannula in the vas for repeated washings should be given up. It was these attempts that led to reflux of the chemical injected and to subsequent stricture formation. It was found that stricture might result whatever chemical antiseptic was used for the injection. It was not the nature of the antiseptic, but it was the reflux of the antiseptic into the interstitial tissues that caused the stricture. Since colloid silver is found in practice to be the most efficient antiseptic, it should be used in preference to any other so far suggested, such as acriflavine.

The operation should not be carried out in the out-patient department. Patients should be confined to bed for two or three days at least, preferably four to five days.

Technique of Vasotomy.

The operation can be carried out under local or general anæsthesia. If a local anæsthetic is preferred, it is administered as follows. Pick up the cord at the top of the scrotum and inject into its substance 5 c.cm. of 1 per cent. novocaine adrenalin solution. Choose the site of the skin incision near the top of the scrotum and inject along this with a fine needle some 10 c.cm. of ½ per cent. novocaine adrenalin solution.

---

[1] Jour. Amer. Med. Assoc., 1905, xliv., 1277.

The vas should be isolated beneath the scrotal skin with the gloved fingers or a special clamp and a small incision be made directly down until the coverings of the vas are exposed. The vas is caught by a pair of sharp-toothed Volkman's forceps and held up in the left hand. With a few touches with a sharp knife the outer coatings of the vas are cleared until the flat handle of a scapel can be gently insinuated between the vas and the other structures of the cord. This is thrust through so as to keep the vas well out of the wound, after which any bleeding points that need attention should be securely ligatured. The vas must be well cleared of the surrounding tissue sheaths, an important point. With a fine-pointed tenotone a tiny opening is now made in a longitudinal direction through the wall of the vas so as to expose the lumen. This can soon be learnt by practice and is the most delicate part of the operation. A fine stiff length of silkworm-gut is now threaded into the vas and will usually pass easily for some 10 in. towards the vesicle. In some cases inflammatory strictures of the vas or inspissated pus will prevent the passage of this gut, in which case it may be thought advisable to desist from injecting the vas. If the lumen is patent a thin sling of gauze is inserted under the handle of the scapel to steady it and catch any drops of escaping fluid. A blunted needle (gauge 20) attached to a well-fitting syringe filled with 10 c.cm. of 5 per cent. colloid silver is insinuated into the lumen of the vas, great care being taken not to rub up the mucous membrane with the point of the syringe. Those who have had little practice are advised to inject sterile water to see if the passage is clear before resorting to the main injection. Five c.cm. of 5 per cent. colloid silver are then slowly injected and should flow easily away to fill the vesicle and ampulla. If 5 c.cm. flow in quite easily, a further 5 c.cm. may be injected. After a pause the syringe is removed and the opening in the vas most carefully closed with one or two 00 catgut sutures. These sutures should only take up the outer coat of the vas and should effectually prevent all reflux of the chemical injected. The vas is then dropped back into place and the skin united with a catgut stitch.

The patient should be confined to bed for at least three or four days to prevent complications, as a little fever is not unusual. The colloid silver may not appear in the urine for many days after the injection. In such cases the effect is always curative. Cures of the infected vesicle will be obtained in the majority of the cases by one injection. If a cure is not attained, then the vas can be exposed a second time a week or ten days later, and the injection repeated at a site a little higher up. In this way risk of stricture and sterility is avoided and the desired result is obtained.

Indications for the Operation.

The agreed indications for the operation are as follows: In all cases of non-tuberculous seminal vesiculitis without intense perivesiculitis refractory to non-surgical treatment due to the gonococcus, colon bacillus, streptococcus, and other pyogenic bacteria: (*a*) causing a chronic urethral discharge; (*b*) aspermia or necrospermia with sterility; (*c*) bacteruria and rigors; (*d*) arthritis or myositis; (*e*) attacks of recurrent epididymitis; (*f*) chronic cystitis following prostatectomy.

The diagnosis is established especially by careful rectal palpation of the vesicles with the trained and expert finger, the presence of necrospermia and pus in a condom specimen of the sperm, persistent relapsing swellings of the epididymis, and bacteriological investigations of the spermatic fluid. Experience can alone decide as to whether the operation must be carried out on one or both sides in any particular case. It is not always necessary to operate on both sides.

Vasotomy in Gonorrhœa.

Recently vasotomy has been advocated for all cases of acute gonorrhœa. I have been so impressed by the immediate and rapid cure of cases of chronic vesiculitis where no other treatment has been employed, except a single lavage of one or both vesicles, that I am quite prepared to believe that lavage of the vesicles on one or two occasions might rapidly cure recent acute gonorrhœa. Kenneth Walker's experiments on animals and certain clinical features of urethritis are suggestive in this connexion. The results of experience can alone decide such a question. The operation of vasotomy has come to stay. It must remain an operation to be practised only by those who are willing to give up some time to learning accurately the technique, and should not be condemned by those who have had no experience of it or who refuse to follow the minute steps necessary for success. I have had many striking results with it in a series of extremely difficult cases.[2] I cannot too strongly call for its consideration by those who are in charge of venereal disease clinics and military and naval hospitals.

DEATHS AND DEATH-RATES IN THE MERCHANT MARINE, 1926.

BY FLEET-SURGEON W. E. HOME.

A RETURN[1] published by the Board of Trade summarises the deaths that occurred in 1926 in the mercantile marine. No death-rate for seamen is prepared by the Board of Trade, on the ground that no precise knowledge is available of their number, but only of their deaths. The Board does, however, allow that "the numbers of persons forming the first crews of vessels," stated annually in the above-mentioned return, furnishes "an approximate basis *for estimating* the variations in the extent of the risk from period to period." I have prepared Table I., attempting to use such data as is available from the return and from the Registrar-General's Decennial Supplement on Occupational Mortality (1927, H.M. Stationery Office, 7*s*. 6*d*.), in which (pp. 126–128) is a discussion of the mortality of seamen, 1921–23. This supplement did not appear till 1928.

The total number of deaths of employed or occupied sailors is known, and their causes are nowadays, we are told, being more correctly stated. It is the average daily number of seamen amongst whom these deaths arise of which we are uncertain. Every year the numbers in the "first crews" of ships are published, and every five years a census is taken of all seamen in seagoing vessels, registered in the British Islands, except yachts and fishing boats. This census, taken all over the world on a single day in 1901, 1911, and 1921, showed a number much less than the number given in the return of persons forming "first crews," the proportion being respectively 82 per cent., 81 per cent., and 55 per cent. in the three years. The census in 1921, the latest available, was taken during a coal strike, attended with great unemployment for seamen. What proportion of "first crews" can we then assume to be the number usually employed? I submit that 90 per cent. would in ordinary times be near it, and in 1921 70 per cent., and that these figures may be used, in the words of the Board of Trade, as "an approximate basis for estimating the variations in the extent of the risk." The Board of Trade gives no suggestion of its own idea of these variations, nor until this year has any official figure been put forward; even now no figure is given for occupied seamen, but only fo occupied and retired seamen together.

TABLE I.—*Deaths and Death-rates in the Merchant Marine.*

	1901.		1911–12.		1921.		1926.

* 604 (4 per cent.) drowned in *Titanic*.

In Table I., then, is a statement of death-rates in the merchant marine in 1901, 1911, 1921, and 1926, with the numbers of "first crews"; the number of men supposed to have been daily on board ships in each year, and the deaths from certain causes are also given. The greatest decrease in death-rates in the quarter of a century is in those from alcohol, from 120 deaths (death-rate 0·9) in 1901 to 31 (0·2) in 1926; but the rates for enteric, small-pox, diseases of the circulatory system, suicide, and "all diseases" have *satisfactorily* decreased, for tuberculosis (all forms) rather less, while those for pneumonia seem larger. Except as regards alcohol and suicide the decrease is not large enough to dispel anxiety about the health of the merchant marine. Is it *improving* in health as rapidly as is the population ashore?

Table II. sets out the death-rates of the merchant service in 1926, obtained as has been described, against those of the Navy (1925) and the Army (1926), taken direct from their reports published this year. The death-rate of the Air Force (1926) is calculated from the figures of deaths given in that report, which is concerned with a much smaller total of men than are those of the other services. Next come the merchant service figures of 1926, followed by two columns, calculated from figures on p. 128 of the Decennial Supplement about which some remarks must be made.

TABLE II.—*Death-rates in the Services and the Merchant Marine.*

—	Navy. 1925.	Army. 1926.	R.A.F. 1926.	Merchant marine.		
				"Occupied." 1926. Board of Trade.	"Occupied and retired." 1921–23. Registrar-General.

All causes ..	2·82	2·35	4·6	6·17	10·4	13·5

* Thousands.

When that Decennial Supplement was being prepared some doubts were thrown on the statistics of the occupational mortality of seamen presented in the corresponding report for 1901. These doubts were considered by a departmental committee and (p. 126) it was decided that some better system of measuring the occupational mortality of seamen should be devised; the figures in the last Decennial Supplement are the result.

The uncertainty about the numbers of seamen employed from day to day, the many countries in which their deaths are registered, the loose connexion of seamen with their trade, the readiness with which they drop it when tempted by good conditions ashore or are forced out by disabling illness—these and other difficulties are carefully discussed in Appendix B, On the Mortality of Seamen, in the Supplement. (The corresponding section in the 1901 report was signed by Dr. John Tatham; this comment is not signed.) When the numbers employed had been assembled from the returns of the censuses taken in England and Wales, Scotland, Isle of Man, &c., and at sea, the deaths of seamen had to be ferreted out, those of lascars excluded, and finally deaths and populations were arranged by ages, 20–24, 25–34, and up to 65 years, as is done for all occupations. From these figures comparative mortality figures (C.M.F.) are calculated, showing the deaths that would arise among 100,296 persons in the industry, if their ages were distributed as they are in the standard population (occupied and retired civilian males), and if the death-rate of each age-group had been as in the industry in question. In the standard population. 109,296 occupied and retired civilians, 1000 deaths happened in the year, and when the C.M.F. for seamen has been calculated we find the following figures (p. 218):—

---

[1] Return of Shipping Casualties to and Deaths on Vessels, 1926. H.M. Stationery Office. 1928. 2*s*.

	Respiratory tuberculosis.		Violence.		All causes.
Occupied and retired civilian males	163·5	..	73·6	..	1000
Occupied and retired seamen ..	221·5	..	389·7	..	1768

In the report 178 groups of occupations are discussed, and it is remarked upon that the seamen's C.M.F. from all causes is higher than that of 171 occupations; to which might have been added the fact that the seven higher all have far fewer members. The report proceeds to note that the rate from phthisis is higher than in 131 occupations, "but that for violence is quite beyond the range of land experience. The highest combined suicide and accident C.M.F. in Table C is 236·3, that for conveyors of material to the coal shaft [72,026 persons], which is about 39 per cent. less than that for seamen."

No death-rates for all seamen are given, but they can be calculated from the figures presented, and thus I have obtained the rates in the two last columns of Table II. In one of these columns are given the death-rates of occupied and retired seamen, ages 20–45 for comparison (crude only, the age-distribution being so different) with the service figures, whereas the other gives the death-rates, ages 20–65, for comparison with the death-rates amongst the merchant marine on active service, the seamen occupied from day to day.

We have not yet discovered the true death-rates of seamen in the merchant service; but everyone who reads Appendix B in the Decennial Supplement will realise that seamen, occupied and retired, have an enormous death-rate from violence, and that their death-rate from disease is also extravagantly high. This may be because they are the only large body of British workers whose health is not under medical supervision. The Board of Trade have made no statement indicating realisation of the situation shown by the Registrar-General. The Board may not realise that under their administration seamen have had much higher death-rates than have most other workers who are under the care and supervision of the Ministry of Health. If one thinks of the care the Board of Trade takes of the health of seamen one cannot but recall the bitter words of Alcestis as she thought of the stepmother with whom she saw her children threatened—ἐχίδνης οὐδὲν ἠπιωτέρα, which may be reasonably translated "no kinder than a cockatrice."

SMOOTH AND ROUGH STRAINS OF BACTERIA.

In the days of Koch it was accepted by most bacteriologists that a given species of bacteria was extraordinarily constant in all its characters. When variations were suspected it was found expedient to ignore them in order that a body of knowledge might be built up as to the behaviour of the less variable cultures, whose features were uniform, and whose morphology and physiology was constant. The occurrence of transmutation from one species to another has not been proved, but during the last 20 years variability in certain directions has been gradually accepted and the correlated changes noted and collected.

E. Weil and A. Felix, H. Braun, P. Bruce White, M. Robertson, and others, working with *B. proteus*, *B. paratyphosus*, *B. tetani*, &c., have shown that motile species of bacteria usually contain two distinct kinds of antigenic and agglutinable substances, associated—the one with the flagella, called the H, the other with the body of the bacterium, called the O antigen. Non-motile cultures were also obtained as variants which contained only the O and no H antigen. By these observations they confirmed the earlier work of Smith and Reagh.[1] The H antigen is responsible for agglutination of emulsions by serum in large, loose, flocculent clumps, formed by the entanglement of the flagella: the O antigen especially when present alone, as in the non-motile forms, is revealed by the agglutination of the bodies in small, dense, coherent grains. In normal cultures, of *B. typhosus* for instance, the two substances are present and by varying independently may affect the results of agglutination and other serological tests, since each has its appropriate and independent antibodies. Differences in one or other of these two antigens are responsible for the distinctions between types in the Salmonella group. The H antigen is not demonstrable in emulsions of bacteria which have been heated at 100° C. for one-half to two hours, but the O is thereby unaffected. On the other hand, changes in the O antigen alone are associated with the peculiar serological behaviour of the so-called "rough" variants derived from cultures of certain bacteria; the H antigen remaining unaltered. Indeed this change in the O, sometimes called the somatic antigen, is the main distinction yet recognised between the behaviour of the "rough" and "smooth" strains on which so much work has recently been done. This work dates from 1920, when Arkwright[2] showed that the spontaneously agglutinable variants which could be isolated from old cultures of normal strains of *B. typhosus*, *B. dysenteriæ*, &c., by selecting colonies of peculiar appearance on agar, also had special serological characters indicating considerable deviation from the type in their antigenic content. He called the normal strains, which made turbid growth in broth and from which good permanent emulsions could be made in salt solution, the smooth or S. form, because the round, dome-shaped colonies were shiny on the surface; the colonies of the spontaneously agglutinating (rough) form were irregular in surface and outline. The rough (R.) form could not be made into a permanent emulsion in salt solution, unless the content of salt was reduced to 0·4 per cent. or sometimes even to 0·1 per cent., and broth cultures instead of being turbid became clear with a large, clumped deposit. The R. colonies were not always typically jagged in outline, and shagreened on the surface, but might only appear dull by reflected light, opaque and coarsely granular under the low power. Serum made from the R. form did not agglutinate the S. form, and serum from the S. had only slight action on the R. emulsion. Absorption with R. emulsion removed any R. agglutinins that were present in the S. serum, without affecting the S. agglutinins. A culture might contain pure S. or R. forms only, or a mixture of the two in varied proportions. Very similar observations have since been made on many strains of *B. dysenteriæ*, *B. typhosus*, *B. coli*, Salmonella, and so forth.

The change from the S. to the R. form is usually independent of any alteration in motility. Moreover, as has been noted above, the results of experiments on agglutination and absorption of agglutinins and on the production of agglutinating sera indicate that the change from S. to R. is concerned only with the O or somatic antigen and does not involve any alteration in the H or flagellar antigen.[*] The smooth somatic appears to be changed into the R. somatic antigen. Schütze[3] and P. B. White[4] also showed that strains which differed widely when smooth often had close affinities in the rough form, since this appeared to have lost the specific S. antigen. The independence of the two changes, from H to O and from S. to R. may be shown by obtaining the following four variants from a single motile strain: (1) normal or smooth motile, containing H and S somatic antigens; (2) rough motile, containing H and R. somatic antigens; (3) smooth, non-motile, with only S. somatic antigen; and (4) rough non-motile, with only R. somatic antigen. The permanence of these variants is still a matter of uncertainty. They may all four remain unchanged through many subcultures, but the tendency to revert or change further varies with the strain. Broth cultures of S. tend to change to R. if not subcultured for many days. R. cultures, if free from S. elements, are said to be incapable of reversion, but this is very doubtful.

---

[*] In the U.S.A. P. Hadley and others have used the terms S. and O. in a rather different sense to that defined above. S. has been taken to mean the complete normal form whether flagellated or not, and the O. form has been represented as intermediate between the S. and the R. In so doing, these writers ignore the existence and importance of the H. or flagellar antigen. Their usage appears to be connected with a scheme of cyclic changes in bacteria along definite lines, which is not at present generally accepted.

Changes in Virulence and Pathogenicity.

The significance of these variations has not yet been established, though various isolated observations have shown that they may be connected with changes in virulence and pathogenicity at least in some organisms. It has been found by Topley,[5] Goyle,[6] P. B. White, and others, that in Salmonella and *B. typhosus* the R. form is much less pathogenic than the S. In the case of *B. dysenteriæ* this has not been shown, since both S. and R. forms make strong toxin. There is also experimental evidence that vaccines made with the R. form of *B. paratyphosus* A and *B. typhosus* are much less protective than those made with the S. form. When variants of other classes of bacteria have been examined, somewhat similar facts have been elicited. F. Griffith[7] found that by selecting colonies of pneumococcus with a dull surface he could obtain a variant which he called rough and found to be of very low virulence for mice. This form was not spontaneously agglutinable in salt solution.

In America O. T. Avery, M. Heidelberger, H. Reimann, and L. A. Julianelle have determined that there is a change or degeneration of the antigen of pneumococcus in certain variants which have lost their capsule. This "degraded" form they consider identical with the R. form of Griffith. It has lost its type specificity and is non-virulent, but has agglutinins in common with the R. form of other pneumococci.

They have traced this change to the loss of a definite carbohydrate substance associated with the capsule. Julianelle also found precisely similar R. forms of the capsulated *B. pneumoniæ*. It seems probable that a somewhat similar loss occurs in the change from the S. to the R. form of *B. dysenteriæ*, *B. typhosus*, &c., but the chemical work on this latter group has hardly reached so complete a stage. In the case of the Gram-negative intestinal group and of the pneumococcus, and pneumobacillus, the R. form can be produced by growing the S. form in immune serum. M. Cowan found that certain variants of *Streptococcus hæmolyticus* derived from colonies with uneven surface and outline were less virulent than those from smooth-domed colonies, and that the uneven colonies led to growth in broth with a large deposit and a clear supernatant. She therefore called these variants rough on the analogy of *B. dysenteriæ*. Later observations have shown that irregular streptococcus colonies forming clear broth cultures with large deposit may be more virulent than the smooth-looking colonies which form turbid broth colonies (Todd,[8] Andrewes,[9] 1927–28), and that virulent and non-virulent variants of the same culture may have almost indistinguishable colonies. In fact, the results of work on so-called S. and R. variants of streptococci are at present inconsistent and require further work for their elucidation.

It is desirable even at this stage to give the term "rough" uniform significance, and as far as possible to restrict its use to variants with one set of characteristics. The change in the somatic antigen should be regarded as the most essential change in passing from S. to R. This is almost always associated in the Gram-negative intestinal group of bacteria with spontaneous agglutinability in salt solution, but not in distilled water. The appearance of the colonies is usually a valuable guide to the detection of R. variants, but this is not always the case and R. colonies of the same strain may differ in appearance. It is not clear yet how far the variants described above are merely shifting states within the normal limits of the species. The wide affinities of the R. form suggest an approximation to a primitive state from which more definite types have developed. The suggestion that loss of virulence may occur in the body of an infected animal in connexion with change from S. to R. has not yet been established, but this and other questions are receiving attention from the large number of workers now investigating the anomalies of rough and smooth variants.

THE DAIRY CONGRESS.

THE first three sessions of the Eighth World's Dairy Congress were held at the Central Hall, Westminster, from June 27th to 29th. The Congress has attracted some 2000 delegates representing 42 countries, and the interest shown suggests that the civilised nations of the world are realising that, as Sir George Newman put it, the dairying industry is not only a trade but a service for health. Prof. E. V. McCollum pointed out, moreover, that in countries where dairy animals are abundant the physical development of the population reaches a high standard.

The proceedings on the first day were opened by Mr. Walter Guinness, Minister of Agriculture, who referred to the changes which had been brought about in the last hundred years by urbanisation and the growth of the transport problem. It was possible, he said, that we were now reaching the limits of the distribution of raw milk. The dairy industry in England and Wales was the most important branch of agriculture and the value of its products was about £58,000,000 a year. Dairy herds were increasing and had reached the record figure of 2,800,000. The consumption of milk in England was, however, much too small. Even greater developments with an increased demand would result from public confidence in an improved supply. Mr. J. Maenhaut, President of the National Dairy Society of Belgium, brought greetings from his country, and Dr. F. E. Posthuma, formerly Minister of Agriculture in the Netherlands, described how dairying in Holland had changed from a family industry to a factory business. He held that the owner of the farm should also be part owner of the factory. It was probable that there would be many more milk products in the future. It was necessary to organise both farms and factories on an international as well as a national basis.

The business of the Congress was taken in sections. In the following notes are summarised a few of the numerous communications which had a bearing on public health.

Feeding of Milch Cows.

Mr. R. B. Boutflour (Harper-Adams Agricultural College) drew attention to the fact that an average cow can only efficiently digest 30 lb. of dry food. If it is given 40 lb. its digestive organs are likely to suffer and a diminished supply of milk will result. He emphasised the need to control both the total amount of food and the amount of indigestible fibre and the importance of careful preparation of the cow for her lactation. An adequate supply of water and three milkings in the day produced high yields; many herds now giving an average of 700 gallons per annum could have their output raised by 50 per cent. if attention were paid to these matters. Mr. James Mackintosh (Reading) drew attention to the very varying soils of the districts in which dairying was now carried on, and to the need for adapting the feeds to the crops which could be best grown in the district. Analyses of the district crops was desirable. The use of roots for feeding was chiefly a question of cost. Dr. H. E. Magee (Rowett Institute, Aberdeen) drew attention to the drain on the calcium reserves of the cow caused by heavy milking, and pointed out that if this was not counteracted in the feed and an adequate supply of vitamin D secured at least a reduction of milk, abortion, or tuberculosis might result. An American speaker drew attention to the deficiency of phosphorus in the soil of Minnesota, where adjustments had had to be made for the excess of sulphate of magnesia in the water.

Milk Recording.

Many communications testified to the good work done by milk-recording societies, and it was urged that more could be done through such societies to secure the elimination of dust in the cowsheds and the prevention of tuberculosis. In New Zealand, where the cow and human population are the same—namely, 1,400,000—it was claimed that recording had brought about an increase of 30 to 40 lb. per cow in butter-fat. The milk there is sold according to fat-content. Scotland was mentioned as a pioneer in recording, and there also the creameries pay for milk in proportion to the fat-content. It was pointed out that it is worth while to do the recording twice a day, so that steps can be at once taken to counteract a drop in yield or the beginning of illness. It was also stated that many farmers employed inefficient milkers. One member of the Congress went so far as to suggest the promotion of sweepstakes among the milkers to promote a spirit of competition. Another suggestion put forward was the trial of a longer interval between calvings—e.g., 15 or 18 months. The need for a standardisation of milk records was put forward by Prof. Prawochenski (Poland) and other speakers.

Grading of Butter and Cheese.

From Australia, New Zealand, and Canada came the information that the grading of butter and also of cheese had by instigating competition amongst the manufacturers produced a great improvement in quality. There was some discussion as to the want of agreement in the grading of the same butter before it left Australia and after it reached London, and it was also pointed out that the system of grading might be helped if steps could be taken to enable the consumer to know what grade he was purchasing.

Milk Control and Designated Milk.

Many papers dealt with the question of control of the milk-supply, and there was general agreement that the best control was by the banding together of producers who believed in sound work and realised that success lay in securing the maximum number of satisfied customers. There appeared to be complete unanimity that the cost of control and inspection by the central and local governing bodies was for the good of the whole nation and should be borne by the taxpayer rather than by the ratepayer. Much was said with regard to designated milks in this country. Among the points made were the need for a much greater incentive for the production of Certified Milk and for a change of nomenclature. The titles of the designated milks were admitted to be most misleading, and " Grade A " was frequently thought by the public to be the best class of milk. Mr. Wilfrid Buckley drew attention to the fact that even a recent British Red Cross publication had fallen into this error. Sir George Newman agreed that the present nomenclature was unsatisfactory and asked the Congress to supply a unanimous suggestion for its amendment. He also pointed out, when the usual controversy between advocates of clean milk and pasteurised milk respectively arose, that pasteurisation and the production of clean milk were not really antagonistic aims. Pasteurisation might make dirty milk safe, but it could not make dirty milk clean. Several speakers pointed out that milk in the U.S.A. was graded before it was pasteurised, and others urged that in this country all milk except that from tubercle-free cows should be pasteurised.

Various Milk Products.

As compared with previous national milk conferences, there was evidence of a broader view as to the uses of milk. Captain J. Golding (Reading) said that the Dairy Institute was not sufficiently alert to prevent the waste of milk by-products, such as whey and skimmed milk. The addition of skimmed milk greatly improved bread. Mr. H. E. van Norman (Chicago) said that American bakers were successfully mixing dried skimmed milk with flour for baking in the proportion of 3 per cent. to 8 per cent. Skimmed milk was also being used for the manufacture of biscuits and ice-cream. Mr. F. Rasmussen, Secretary of the International Association of Ice Cream Manufacturers, showed that ice-cream was now an important food in the U.S.A. Nearly as much milk was used to make ice-cream as to make cheese, and the consumption had gone up from one gallon per head per annum in 1905 to about three gallons in 1926. Nearly £100,000,000 was invested in its manufacture. About two-thirds was consumed in the four summer months and absorbed the summer surplus of milk, thus helping to stabilise prices. The ingredients were milk products, plus sugar and flavouring agents, and the average ice-cream contained 22 per cent. of milk solids. The manufacturing associations hoped further to increase the sale by supplying housewives with ice boxes. Prof. A. Mertens (Louvain) said that Belgium was following the lead of America in the matter of ice-cream. Interest in the ice-cream question gave rise to a special session.

The Rôle of the Veterinary Surgeon in the Improvement of the Milk-supply.

Two sessions were devoted to this question. The discussion brought out a strong feeling that biological tests and routine veterinary inspection should be compulsory and universal, and that the veterinary inspection should not be limited in its purpose to the control of tuberculosis, but should be utilised for improving the feeding and hygiene of the cattle. Dr. W. G. Savage estimated that the cost of inspection would be approximately from 1s. 6d. to 1s. 8d. per cow per year, which meant from a quarter to one-third of a million per annum for England and Wales and from £10,000 to £14,000 for his own county of Somerset. This cost was a heavy burden on poor agricultural counties, mainly for the benefit of urban areas. Prof. Porcher said that veterinary inspection was not compulsory in France, but had been made optional for the departments. An able paper by a veterinary surgeon, Mr. Trevor F. Spencer (Kettering), expressed the view that the present legislation as administered was doing nothing to reduce the prevalence of bovine tuberculosis and that a much more determined effort was needed. There was very little regular veterinary inspection. His views (as to the futility of the present administration of the law) were largely in accord with those expressed in THE LANCET last year by Dr. Savage. With a proper effort the expense of dealing with tuberculosis should be a decreasing one year by year. Under present conditions the expense would be a continuous one. Mr. Spencer's paper caused considerable discussion as to whether the local knowledge of the part-time veterinary surgeon outweighed the disadvantage caused by the conflicting interests of his private clients, and also brought out the fact that, while veterinary inspection was not appreciably used in England and Wales, it was in full operation in most of the dairying counties of Scotland. Several speakers blamed the Ministry of Health for failure to encourage the application of veterinary inspection in England and Wales. Most of them were inclined to think that the first step with regard to tuberculosis was the general enforcement of present legislation with an encouragement of designated milks and a gradually increasing stringency of the enactments and that the time was hardly ripe for new legislation or the extended use of the tuberculin test. Mr. Hugh Begg (county veterinary inspector, Lanark) pointed out that 75 per cent. of the tuberculous cows were aged and that more attention might be given to killing off aged cows. Mr. A. Gofton (veterinary inspector, Edinburgh) referred to the insufficient liaison between the departments of agriculture and health, and pointed out that most of the burghs of Scotland had had veterinary inspectors for 25 years. Captain R. Simpson (veterinary inspector, Cumberland) was as optimistic as the Scottish speakers as to the good effects of present legislation in his county. Prof. Ostertag took part in the discussion. A breeder of pedigree stock, timorous as to the use of tuberculin, was promptly answered by another pedigree breeder (Hon. G. Corbett, Ayrshire), who pointed out that it was essential for anyone who produced for export to have tubercle-free herds. He added that they hoped soon to have special accommodation and special prizes at the Highland show for tubercle-free animals. He referred to the danger of infection from manure and mentioned two precautions which he had adopted—namely, double fencing of the fields used by the tubercle-free cattle, and, in the event of reactors being found at the half-yearly testing, the segregation of the two neighbours of the reactor, until it was certain that they were not infected.

Food Value of Milk and Propaganda.

There were many papers on the food value of milk. Prof. McCollum referred to large scale experiments on the gain to American school-children from an extra allowance of milk, and Prof. Pirquet (Vienna), after referring to the similar experience of Dr. Corry Mann and Dr. G. A. Auden in England, mentioned that the use of milk was increasing in Austria. There were many papers on methods of propaganda, and Dr. Ernest Eber (Hungary) moved a resolution for the establishment of a central office in London for the organisation of dairy propaganda throughout the world. This resolution was referred to the Executive Committee. The question of the education of those engaged in the dairying industry produced communications from Dr. Stenhouse Williams, Dr. Otto Gratz, of Hungary, and Dr. F. Zaribnicky, of Vienna.

The Congress also held sessions in Reading and Edinburgh; many tours of professional interest to its members are being made, and the Congress will not conclude until after the meeting of the Royal Agricultural Show at Nottingham, July 10th to 12th.

Conclusion.

The arrangements for the sessions and tours brought credit to the organising ability of the secretary, Mr. Arthur D. Allen, and the tone of the discussions justified the contention of Mr. Walter Guinness at the outset, that although the delegates to the Congress were competitors and in the markets of the world, they were coöperators in education and research.

LEAGUE OF NATIONS.

AN INQUIRY INTO THE RADIOTHERAPY OF CANCER.

THE Subcommission of Experts charged by the Cancer Commission of the League of Nations with the study of Radiotherapy of Cancer held its first preliminary meetings on June 18th and 19th. These were attended by the President of the Cancer Commission, Sir George Buchanan, senior medical officer at the British Ministry of Health.

This subcommission included the following experts in radiology and gynæcology:—

Prof. Cl. Regaud, Director of the Radium Institute of the Curie Foundation, Paris (President).

Dr. C. Comyns Berkeley, Director of the Middlesex Cancer Charity Hospital, Gynæcological Service.

Prof. Döderleim, Director of the Gynæcological Clinic of the University, Munich.

Prof. W. Lahm, Director of the Laboratory Research Work, the State Gynæcological Clinic, Chemnitz.

Prof. van Rooy, Director of the Gynæcological Clinic of the University, Amsterdam.

M. R. Ferroux, Chief of the Therapeutical Works at the Curie Foundation, Paris.

Prof. Voltz, Gynæcological Clinic of the University, Munich.

Investigator: Dr. Janet E. Lane-Claypon, attached to the Departmental Cancer Committee of the Ministry of Health, London.

Prof. G. Forssell and Dr. Heyman, of Radiumhemmet, Stockholm; and Prof. Pestalozza, Director of the Gynæcological Clinic, Rome, were absent.

The subcommission was appointed in consequence of a report by the Cancer Commission to the Health Committee of the League in May last, in which emphasis was laid on the importance of collecting data from different sources regarding the methods of radiological treatment and their modern results. In addition, it was suggested by the President of the Cancer Commission that it might be well for the subcommission to take cognisance of the following points: 1. Available supplies of radium. 2. The centralisation of radium in each country for the supply of the smaller clinics and individual practitioners, in the event of this being considered desirable. 3. The form of record which should be kept with the view of comparing the results obtained in different countries after some five years' observation after cessation of treatment.

The subcommission first considered in detail the nature of the information to be collected and the sources to which application should be made. It was considered necessary to obtain individual details of a, numerically, large series of cases of cancer of the uterus divided according to their treatment (*a*) by radium, (*b*) by X rays, or (*c*) by both—taking account only of those cases in which the treatment was completed more than three years ago, and in which the after-histories were traceable; it will also be necessary to have statistical data of all observed cases in each of the clinics taking part in the inquiry. The details to be given were settled, but the subcommission left the preparation of model forms, cards, &c., to the Health Secretariat, which for this purpose will have the advice of Dr. Lacassagne (Paris), Prof. Voltz (Munich), Dr. Heyman (Stockholm), in addition to that of Dr. J. E. Lane-Claypon, who has been appointed the technical inquiry officer of the Commission for this purpose. The same group of experts will assist in the collection and codification of the replies received.

The clinics and institutions to be applied to are to be limited in the first instance to those which possess a sufficiently large experience, and their assistance may be invited either directly or through national health administrations or other appropriate national organisations. As some cancer or gynæcological clinics have already expressed their willingness to coöperate in an inquiry whose practical value they recognise, it is hoped that those data can be collected without delay. It is intended that the results when analysed should be submitted in the form of a report to the Committee, and published in due course. While the clinics or institutions chosen will be specially requested to follow the system of record proposed to them for purposes of international comparison, they will also be invited to summarise their own observations and views regarding the efficiency of radiological treatment in any manner which they consider may be useful to the Commission. The inquiry as such is to be limited to uterine cancer (cervix and body), but accessory information regarding cancer of other gynæcological sites may be supplied for separate study.

On the broader questions relating to the treatment of uterine cancer by radiology, the President submitted a series of considerations which, after a general discussion, were adopted by the subcommission as representing the most important directions to which its future discussions should be directed, and on which definite recommendations should be made in due course to the Health Committee with a view to publication. Among these considerations were: 1. Propaganda among doctors and the general public in order to ensure the early discovery and early and correct treatment of cancer of the uterus. 2. Increase in the number of consultation centres. 3. Organisation of centres for microscopic analysis in order to ensure early diagnoses. 4. Recommendations for the organisation of the correct treatment of the disease. 5. Recommendations for the radio-therapeutical equipment of clinics. 6. Disadvantages of out-patient treatment. 7. Recommendations for the compilation of reliable statistics. 8. Recommendations for special scientific research.

The Commission also noted, as subject for inquiry, the available supplies of radium and the need for an authoritative opinion as to the advantages and drawbacks of distributing radium or radium emanations to hospitals and individual practitioners.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1927 statistics of six districts :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Diarrhœa, &c., under 2 years.	Maternal mortality from childbirth.
Wiltshire C.C. .. (299,500)	15·4	12·1	0·75	1·41	2·4	2·0	51	2·3	3·5
Sunderland C.B. (162,700)	22·4	13·8	1·38	1·10	3·2	1·8	94/41	14·2	4·7
Edmonton U.D. (71,279)	17·8	10·9	1·23	1·0	2·4	2·1	61	7·1	0·8
Doncaster R.D. (41,760)	24·1	9·8	0·76	0·74	2·2	0·8	76	7·9	3·9
Ramsgate B. .. (30,100)	15·0	15·0	1·10	2·0	2·9	1·7	69/33	4·0	0·0

Wiltshire.

Dr. Claude Tangye says there are still two obvious gaps in the county administration. The first is that children, apart from special cases, do not between the age of 1 year and school age receive the supervision which is urged by the Ministry. Provision has been made in the current estimates for an increase in the health visiting staff for this purpose. The second gap is in the tuberculosis scheme. Hospital facilities both for pulmonary and non-pulmonary tuberculosis are satisfactory but, owing to the inadequacy of the county medical staff, the supervision of cases in their own homes is only partially carried out in the Swindon area, which perhaps needs it most, being densely populated and industrial in character.

The deaths attributed to influenza numbered 313 and exceeded those from bronchitis (225) and pneumonia (188). The epidemic of influenza in the early part of the year accounted to a large extent for the higher death-rate as compared with the previous year, and also caused the closure of 159 schools. With modern ambulance facilities the present number of small isolation hospitals in the county could be reduced. The county council takes the responsibility of dealing with all cases of small-pox which may occur within the county, and the new hospital for the northern district at Ogbourne St. George is now complete.

The water-supply of the towns is good, but many of the villages are dependent upon wells which have become hopelessly polluted and others are dependent upon rain water only. The local authorities are awakening in the matter, and during the year inquiries were held with regard to the water-supply of three of the rural districts. In addition, the water-supply for the parish of Ashton Keynes, chiefly derived from numerous polluted shallow wells, is thought to be associated with the prevalence of intestinal worms among the children, an opinion which is said to have been confirmed by an inspector of the Ministry. As a result the rural district council is considering a scheme for the water-supply of this village. Pure water for these villages and for the farms is doubly important. In the first place, Dr. Tangye says ordinary typhoid fever is making its reappearance. There were 12 notifications during the year with three deaths. In the second place, compliance with the new Milk and Dairies Order is impossible without a pure water-supply, and there is, of course, a great milk industry in the county. The sewage disposal works have also received considerable attention. Of the effluents from 13 urban districts, 12 were classed by the analyst as fair or good, and one as poor. Of the effluents from 15 rural district works, nine were classed as fair to good, while two are described as not good, two as bad, one as very bad, and one as very foul. The Staverton Milk Factory pollutes the Avon in the Melksham district and a very foul effluent is from the Netheravon works, which are under the War Department.

Council houses have been erected in every district except Malmesbury U.D. and Chippenham R.D., and the Chippenham R.D. Council have now decided to build. The Housing (Rural Workers) Act came into force on Dec. 15th, 1926, and up to the end of 1927 20 applications were received. In eight cases grants were approved totalling £1455, and a loan of £100 was made, but two of these applications were withdrawn. Of the remaining 12, ten were refused, one is under consideration, and a grant of £100 was made in 1928 for the other. This Act, says Dr. Tangye, provides the first real opportunity open to county councils for direct help in the improvement of housing conditions, and few counties have wider scope for its operation than Wiltshire.

The follow-up of tuberculous milk samples reported by outside authorities is doing something to eliminate tuberculous cows from the Wiltshire herds. Thus, 22 complaints received resulted in the inspection of 32 farms and the discovery of 19 tuberculous cows. Reports from the London County Council of the premature death of many of the inoculated guinea-pigs led to an investigation of the conditions at other farms with the discovery of dirty conditions of the udder and abscesses, and incidentally of one more tuberculous cow. No satisfactory explanation, however, was found to account for the deaths of the guinea-pigs. The county council is also taking samples of milk for bacteriological examination, and following up bad results by veterinary inspection of the farms. In this way four more tuberculous cows were weeded out.

The county council is offering the assistance of its medical and nursing staff to local authorities, who are prepared to undertake the immunisation of children against diphtheria. Seven cases of encephalitis lethargica, six of which proved fatal, were notified, as compared with 20 in 1926. The county council have decided to pay the cost of a locum tenens for one month to enable a midwife, on the application of a local nursing association, to attend a post certificate course; and they have also arranged to supply pelvimeters at a special rate to the midwives for antenatal work. The midwives sent for medical aid in 26 per cent. of their cases. The doctors' fees paid by the county council amounted to £669, of which £244 were recovered from the patients, the balance being divided between the county rate and the Government grant.

The health visitors inspect boarded-out children for all the boards of guardians in the county except three. Dr. Tangye regrets that this scheme has not been accepted universally, seeing that boards of guardians do not employ, as a rule, an experienced nursing staff for this work.

Sunderland.

Dr. A. S. Hebblethwaite presents his first annual report, having been in charge during the last seven months of the year. The unprecedented rainfall during the summer caused flooding in many of the low-lying areas and drew attention to the inadequacy of the sewer accommodation. Housing conditions in the older and more congested parts of the borough have been improved by the number of new municipal and private enterprise houses built, but the problem of housing the working classes in less crowded houses near their work remains. The work in the light treatment clinic has been increased and arrangements have been made for treating children under the age of 5 years.

Dr. Hebblethwaite especially draws attention to the heavy death-rate from respiratory diseases. Tables are given, which show that since 1918 the pneumonia death-rate in Sunderland has been more than 50 per cent. higher than the English rate and that the bronchitis death-rate in Sunderland has been double the English rate. Of the 249 deaths from pneumonia, 140 were children under the age of 5. Dr. Hebblethwaite hopes that more children suffering from pneumonia will be accommodated in the municipal hospital in future.

Sunderland is now, practically speaking, a water-carriage town, and it is hoped that before long a standard dustbin will be provided for every house under the local Act of 1927. There are now only eight cowkeepers within the borough, keeping approximately 120 cows which are inspected quarterly by the veterinary surgeon.

There were 47 cases of small-pox notified with one death at the age-period 45–65. An outbreak at a common lodging-house with 90 male inmates caused considerable trouble owing to the refusal of vaccination by the contacts. The first case was removed on Sept. 13th, the second on Sept. 17th, the third on Sept. 30th, the fourth on Oct. 8th, the fifth on Oct. 9th, and the sixth and seventh on Oct. 10th. After each removal thorough disinfection was carried out and the lodging-house was closed to new applicants from Sept. 13th. After the last removal most of the contacts who needed vaccination accepted it. Eight cases were notified from the Highfield Poor-law Hospital, and the remaining cases occurred in various parts of the borough. There were 11 notifications of encephalitis lethargica, and ten deaths from this disease, five of which were of cases notified in the previous year. Of the 11 cases notified in 1927, five cases died in 1927, one in 1928, four are still suffering from some disablement, and one has recovered.

Edmonton U.D.

Dr. H. W. Harding describes his district as one of the dormitories of London, from which many of the inhabitants travel to town daily. The greater portion of Edmonton is in the valley of the Lee and only slightly higher than its waters, and Dr. Harding suggests that such a site may be responsible for throat affection, enlarged tonsils, and endemic diphtheria. Housing conditions are far from satisfactory. There is still overcrowding and there are various blocks of houses which should be dealt with as soon as circumstances permit. The day nursery registered 7000 attendances. The cost was about £960, of which about £220 was paid by the mothers in fees. The nursery also takes, as residents, the children of mothers who have been taken from home owing to illness; and the full number of 180 school-girls attended the mothercraft classes during the year. The Education Committee contributes £50 to the funds of the nursery in return for the holding of these classes. The joint orthopædic clinic, which provides treatment for crippling defects in children under 5 years and of school age, is conducted by Mr. J. B. Barnett, of the Royal National Orthopædic Hospital, and operative treatment, when necessary, is carried out at Stanmore Hospital. By arrangement with the guardians the maternity wards of the North Middlesex Hospital are used for municipal patients. The fee charged to the council is 6*s*. per day and the order for admission is signed by Dr. Gertrude Outram, who is in charge of the antenatal clinic. The same hospital has also provided, since early in 1927, artificial sunlight treatment for cases of rickets and marasmus.

Doncaster R.D.

Dr. A. B. Dunne says the needs of the district have long since outgrown the existing accommodation of the Doncaster Royal Infirmary and a contract has been signed to build the first block of the new infirmary on a spacious site on the Thorne-road, Doncaster. Dr. Dunne refers to a difficulty caused by speculators buying land and builders erecting a large number of small houses with the assistance of the Government subsidy. These houses have been passed by the council with the drainage emptying into cesspools and the duty of cleansing the cesspools falls on the owner or occupier. The council are now taking steps to meet the difficulty by instituting sewage disposal works for the respective parishes, but the council's schemes must necessarily come later than the building schemes. Dr. Dunne also refers to the increase of atmospheric impurities owing to the growing number of colliery stacks and miners' houses. He suggests that the miner's house produces an exceptional amount of domestic smoke owing to the "home coal" allowance of 1 ton per month to each coal-miner. He looks to the chemists to provide a cheap and smokeless household fuel as a remedy. Dr. Dunne also wonders, in view of universal baths, for how many years the red sandstone can be tapped without encroaching on its capacity, and states that the level of the water in several of the deep boreholes has been lowered. There were 118 notifications of small-pox with one death. The one death was that of a woman of 61, who had been vaccinated in infancy and contributory causes of her death were phlebitis and "petit mal."

Ramsgate.

Dr. W. J. Bannister reports a rainfall of 30·1 inches and a sunshine record of 1647·1 hours. He enumerates the advantages of Ramsgate as a health resort and mentions that a certain number of parents take up their residence in Ramsgate with the object of restoring their delicate children to robust health. From the high infant mortality-rate and the school report one gathers that insufficient attention is given to the children of the normal population. There are nine public elementary schools, of which only the two provided by the education authority and one of the "non-provided" are satisfactory, while in the case of the other six faulty design and unsuitable situation leave much to be desired. This state of affairs, no doubt, makes Dr. Bannister's plea for an open-air school and open-air classes all the year round the more urgent. Verminous conditions give trouble in the schools. There are no school baths and there is no organiser of physical training. Dr. Bannister also pleads for the formation of classes with a view to corrective exercises for postural defects. Each of the four health visitors carries out all the health visiting and school work in the area allotted to her. At the end of the year 198 of the 352 houses in the council's scheme had been provided and contracts had been made for the erection of 38 parlour and 104 non-parlour houses, of which the latter will help to remove the pressing need for housing accommodation at low rentals. During the year an improvement scheme for an unhealthy area was approved by the Ministry.

Yeovil.

Dr. C. W. Gee reports that the staple industry is the manufacture of leather gloves, including all processes from the preparation of the raw hides. The water-supply is not sufficient during dry periods for the area supplied, and the council have obtained powers to sink a new well in the greensand at Cattistock, from which an additional daily supply of 500,000 gallons is expected. Very few houses in the borough are provided with sanitary dustbins and a great nuisance is caused by the blowing about of refuse on windy days.

There were 243 births and 52 expectant mothers attended the antenatal clinic. The general standard of housing is fairly good, but there are many worn-out houses which cannot be made reasonably fit for habitation and which would be condemned under normal conditions. Of 191 new houses erected, 168 formed part of a municipal scheme.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Average elementary school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.†
Shrewsbury	3,900	—*	1,575	6,586	10·3
Bootle ..	12,010	10,804	3,751	12,705	22·5
Taunton ..	2,827	2,616	793	2,404	18·4

* Not given. † Excluding dental defects and uncleanliness.

Shrewsbury.

By the reorganisation of his present nursing staff and the addition of another nurse Dr. A. D. Symons proposes to conduct an increasingly intensive campaign against personal uncleanliness, which perhaps more than any other single condition indicates parental ignorance or neglect.

This reorganisation will coördinate the maternity and child welfare work with the school service by enabling each nurse to carry out all the nursing duties of both services in her own district. In summarising the results of his work for the year Dr. Symons has taken the opportunity of pointing the way to achieve further improvements in the health of the children of Shrewsbury. His proposals include better ventilation and lighting in the schools and bigger playgrounds with shelters for open-air classes, and he has published a special memorandum on "The School Building in Relation to Health," in which his ideas are clearly set out. The provision of milk and cod-liver oil for necessitous children has been justified by their increase in height and weight. The need for further dental assistance will be met by additional dental sessions. Close coöperation exists between the S.M.O. and the organisers of physical training not only in the arrangement of games and sports, but in the supervision of remedial exercises where these are necessary. Acknowledgment is made of the cordial help of teachers, attendance officers, and voluntary associations. That Dr. Symons's good work is appreciated by the parents is shown by the increasing numbers who attend medical examinations and clinics.

Bootle.

Dr. F. T. H. Wood, S.M.O. and M.O.H., in his introduction to this report. points out that the functions of the local education authority go beyond the promotion of the mental development of the child and are actively concerned with his health and physical development. Medical inspection is conducted for the most part by Dr. Purser Davies, who also deals with maternity and child welfare. The tuberculosis officer, Dr. R. Hannah, also helps in medical inspections and at a minor ailment centre. Dr. Wood himself occasionally conducts routine examinations and undertakes the medical work in connexion with the special classes and the Mental Defective Act cases. Meals are provided by the school canteen committee, of which the S.M.O. is a member; this committee has control of a useful fund for providing needy children with clogs during the winter months.

The remedial exercises clinic is supervised by the S.M.O. with the coöperation of an orthopædic surgeon; this clinic deals with mouth-breathers and cases of minor spinal curvature, as well as more definite pathological conditions. The special interest taken by the local authorities in physical development is shown in a further grant of £200 for expenditure on apparatus, and the appointment of a special (playing fields) subcommittee to find suitable playing accommodation. A striking improvement in personal cleanliness and in the attendances at the minor ailment centre is recorded this year, also a reduction in the percentage of most of the physical defects. The hygiene of the mouth and teeth is the subject of a booklet which has been prepared by the Dental Board and circulated among head teachers with excellent results in this town. Teachers have been zealous in passing on information to the children, with the result that further dental assistance will soon be called for. It has not yet been possible to establish any special schools, but the children in the special classes for the dull and backward have been under the supervision of the S.M.O. and all have been individually examined.

Taunton.

In a small town facilities such as clinics and special schools are difficult to establish, but a compensating advantage is that since nearly all the health work is directly under one person coördination is excellent, and intimate contact with parents can be secured. In Taunton Dr. J. Allen, who is in charge of public health, school inspection, and infant welfare clinics, gets a high percentage of parents (72 per cent.) to attend the medical inspections. Moreover, the fact that one person serves both as school nurse and attendance officer leads to the early discovery of infectious and other diseases. The dentist, Mr. A. J. Percy, states that both parents and children are becoming more favourably disposed toward the idea of having teeth filled rather than removed. This preference is a feature of the practice at Taunton, for with permanent teeth the fillings (594) are over eight times as many as the extractions (72). The dentist anticipates that every year 50 per cent. to 60 per cent. of the children will need treatment; but in view of the thorough and prompt work now being done some reduction may, we hope, be looked for.

Taunton is spared some of the disadvantages of a small town, since it is the headquarters of several institutions belonging to the county of Somerset—for example, the orthopædic clinic of the county council is open to the children and the infants of the borough, as is also the tuberculosis dispensary. The occupation centre of the Somerset Association for Mental Welfare is available for low-grade mentally defective children. Dr. Allen mentions that this valuable institution is in urgent need of more local support.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 23RD, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 230 (last week, 282); scarlet fever, 1716; diphtheria, 969; enteric fever, 54; pneumonia, 769; puerperal fever, 47; puerperal pyrexia, 100; cerebro-spinal fever, 10; acute poliomyelitis, 9; acute polio-encephalitis, 2; encephalitis lethargica, 31; dysentery, 8; ophthalmia neonatorum, 117. *No* case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 21 counties: London, 11 (Bermondsey 1, Hackney 1, Southwark 1, Wandsworth 8); Bedford, 6 (Bedford 2, Luton 4); Derby, 28; Devon, 1; Durham, 62; Gloucester, 2; Hertford, 1 (Bishop's Stortford); Lancaster, 11; Middlesex, 1 (Wembley); Norfolk, 1; Northampton, 4; Northumberland, 14; Nottingham, 6; Soke of Peterborough, 1 ; Stafford, 16 ; Surrey, 1 (Godstone) ; Warwick, 2 (Coventry) ; Worcester, 1 ; Yorks, North Riding, 4 ; West Riding, 28 (last week 56) ; Glamorgan, 7 ; Monmouth, 22.

The numbers of cases of small-pox in London have declined during the last three weeks, the figures being 49, 24, and this week 11.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on June 26th-27th was as follows : Small-pox, 69 under treatment, 7 under observation ; scarlet fever, 1781 ; diphtheria, 1979 ; enteric fever, 18 ; measles, 600 ; whooping-cough, 152 ; puerperal fever, 21 (plus 19 babies) ; encephalitis lethargica, 68 ; poliomyelitis, 1 ; "other diseases," 24. At St. Margaret's Hospital there were 14 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were 6 (0) deaths from enteric fever, 34 (8) from measles, 5 (4) from scarlet fever, 48 (7) from whooping-cough ; 29 (8) from diphtheria, 36 (12) from diarrhœa and enteritis under two years, and 31 (3) from influenza. The figures in parentheses are those for London itself.

The six fatal cases of enteric fever occurred at Hornsey, Bath, . Ashton-under-Lyne, Huddersfield, Halifax, and Newcastle-on-Tyne.

The number of stillbirths registered during the week was 258 in the great towns, including 38 in London.

THE EARLY DIAGNOSIS OF CANCER OF THE COLON AND RECTUM.

To the Editor of THE LANCET.

SIR,—Dr. A. F. Hurst, in the admirable paper published in your issue of June 23rd, puts forward a plea for a definite diagnosis of malignant disease of the colon with view to early, and therefore probably more successful, operation. But even when the patient first complains of suspicious symptoms it may be already too late, and all physicians must have met with cases in which the disease had certainly been in existence for a long time without very marked symptoms. A striking case in point recently occurred at the Italian Hospital. A woman, aged 49, was admitted under my care on June 23rd. She was well nourished and had "enjoyed good health" all her life. She had no abdominal symptoms whatever until a week before admission, when she began to suffer from flatulence and constipation, which became complete two days before admission. The abdomen was somewhat distended, but not tender or rigid ; there was no fever, no pain, no vomiting, the pulse and general condition were good. Per rectum nothing could be felt. Castor oil and high enemata failed to produce any evacuation and, since the patient vomited once, and colicky pains appeared, laparotomy was performed by Dr. Lwow, the resident medical officer. On opening the abdomen, gas escaped and free purulent fluid was found. A mass of malignant disease completely constricted the upper part of the sigmoid and a mass of glands in the pelvic mesocolon. The bowel was ruptured above the seat of the disease ! A provisional diagnosis of sclerosing cancer in some part of the intestines, with impaction of fæces above, had been suggested before the operation, but no one who saw the case was prepared for the gross and catastrophic lesions which must have existed for a long time previous to her admission without causing any symptoms to arouse the least suspicion.

I am, Sir, yours faithfully,
T. VINCENT DICKINSON.

Sloane-square, S.W., July 2nd, 1928.

A SIMPLE HOOKWORM LARVICIDE.

To the Editor of THE LANCET.

SIR,—The letter of Col. Clayton Lane in your issue of May 19th on the effect of common salt in destroying hookworm larvæ recalls an investigation carried out by me some seven years ago in an Indian salt mine.

As part of an inquiry ordered by the Government of India into the incidence of hookworm disease amongst miners (of all sorts), it became my duty to report upon the health of the miners employed in the Khewra Salt Mines, which are located in the Salt Range in the north of the Punjab. The health of this community was notoriously bad, and it was generally assumed that ankylostomiasis was mainly, if not solely, responsible. I accordingly set up a laboratory at Khewra and made a systematic examination of the health of the community, which included an examination of the fæces of a large proportion of the miners, and of their wives and families. To my profound astonishment, although the majority of the miners were found to be infected with one or more helminths, not a single ovum of an ankylostome worm was detected. It is now known somewhat more definitely than in the year 1921 that ankylostomiasis is not a common disease in the Punjab ; but, as a result of recent observations at the Mayo Hospital, Lahore, at the Medical School at Amritzar and, more especially, of the helminth survey of India carried out by Dr. Chandler, of the Calcutta School of Tropical Medicine, it has been established that infection with ankylostome worms (not necessarily associated with clinical signs of ankylostomiasis) occurs with some frequency in the hill tracts of the Punjab and somewhat sparsely amongst the inhabitants of the plains. This being so, it is even more of a matter of surprise that a community, working under extremely unhygienic conditions and in an environment apparently favourable to infection (on account of great heat and humidity, work has to close down in the mines during the monsoon months, July to September), should escape completely. I made the suggestion in my report, which unfortunately was not published and which is not now available, that the heavy impregnation of the soil with common salt might exercise an inimical influence upon the hookworm larva during its extra-corporeal phase, and that this circumstance might be responsible for the remarkable immunity of the miners from ankylostomiasis.

Malaria was proved to be the chief cause of ill-health of the miners at Khewra, and no attempt was made to follow up the above suggestion or to determine, by experiment, whether it was well founded ; but in view of the experimental work of Lambinet and others, to which Colonel Clayton Lane alludes, it seems certain that transmission of infection would be impossible in a soil heavily impregnated with salt and that this circumstance might account for the absolute freedom of the Khewra miners from infection. The free use of common salt in coal and other mines, where ankylostomiasis constitutes a menace to health, would thus appear to constitute, as Colonel Clayton Lane remarks, a simple and effective remedy for eradicating hookworm infection from mines ; but surely one may go further and say that the use of common salt would prove equally valuable in all areas, such as the vicinity of latrines, where infection is peculiarly liable to be contracted.

I am, Sir, yours faithfully,
C. A. GILL.
Lt.-Col., I.M.S.

Simla, June 14th, 1928.

PERICARDIAL KNOCK.

To the Editor of THE LANCET.

SIR,—The case of pericardial knock described in your issue of June 16th by Dr. W. A. Lister recalls a certain soldier, whom I saw, in consultation, at the Bermondsey Military Hospital during the war. On approaching the patient, and when still some yards from the foot of the bed, both his heart sounds could be heard clearly. There was no marked constitutional disturbance, so that the heart's action was not accelerated. The result was that the effect produced on the ear resembled that of a grandfather clock. The history was that this phenomenon had been observed for nearly two days. On examining the chest there was evidence of the presence of fluid on the left side, and an exploratory puncture was advised. The chest was not, however, explored, for a few hours later a bronchial fistula developed; the patient coughed up the contents of an empyema, and the heart sounds became normal. The fact that the conduction of the heart sounds disappeared when the pressure of the empyema was removed gives support to Lister's view as to the cause of their conduction—viz., that the sounds arise in the left pulmonary artery, that they are due to tension or distortion of that vessel, thus partially obstructing it, and that they are analogous to the sounds heard when estimating the blood pressure by auscultation. If this is the right explanation, the term "pericardial knock" seems to be a misnomer.

All the other cases have been in association with a wound of the chest—indeed no such case, prior to Lister's, appears to have been recorded in civilian practice. The loudness of the sounds also renders the Bermondsey case notable, for only in Munden's[1] patient, whose heart sounds could be heard 6 or 8 ft. from the chest, and for an hour only before death, was anything like the same loudness recorded. Maynard Smith[2] states that the sounds may sometimes be heard when standing at the foot of the bed, but he makes no reference to their having been heard further off than this. Finally, Rees and Hughes[3] state that the sounds could not be heard at a greater distance than a few inches from the chest in any of the cases which they had collected.

I am, Sir, yours faithfully,

H. E. SYMES-THOMPSON.

Wimpole-street, W., June 27th, 1928.

VARICOSE ULCERATION: ULTRA-VIOLET LIGHT AND UNNA'S PASTE DRESSINGS.

To the Editor of THE LANCET.

SIR,—In answering Dr. Weinbren's criticism in THE LANCET of June 23rd, of my paper on varicose ulcers in the number of May 5th, I must express my regret that some of the points at issue relate to figures in the statement of details (Table C) which unfortunately had to be omitted for reasons of space. This table, as was noted in a footnote to my article, is available for inspection by anyone interested.

1. It is stated in my paper that a relatively large proportion of suberythema doses were given because the ulcers having them "on the whole ran a more favourable course than those having stronger doses." In other words, the smaller percentage of stronger doses is directly referable to their inefficacy. In those cases in which they were used (in 83·8 per cent. of 31 cases for the air-cooled, and 19·3 per cent. for the water-cooled lamp) they were abandoned after what was, in my judgment, a reasonable trial of consecutive doses when, and only when, there appeared to be no justification for their continuance. Since Dr. Weinbren does not give the total number of doses concerned in his calculation, the percentages convey very little. Ten per cent. of doses with the water-cooled lamp in a total of, say, 1000 doses, would represent a very appreciable trial, whereas 10 per cent. of 10 doses would indeed be negligible.

2. The ulcers were treated twice or thrice weekly except, as stated, in the few cases in which an unusually strong dose was given. The figures of duration of the light treatment in the addendum have doubtless misled Dr. Weinbren, because they relate to the whole period during which no treatment other than ultra-violet was given, and they therefore include in certain cases deliberately planned intervals for observation between sets of consecutive doses. It was always possible that intermittent treatment would be actually beneficial when the results of continuous treatment were unsatisfactory. The scheme of dosage would have been more clearly seen had I indicated when these intervals occurred, even at the risk of making the table still more cumbersome. Without this indication an accurate analysis on the lines attempted by Dr. Weinbren is in no way possible.

3. I greatly regret the oversight which led to the omission of the unmeasured ulcer, which "covered three-quarters of the leg," from the irradiated series. The addendum shows that this ulcer was not treated with Unna's paste; the surgeon-in-charge advised amputation.

I can see no indication in the report that the "worst ulcers" were treated with Unna's paste. If this assumption is based on the fact, as stated, that the area of the largest ulcer in the Unna series was greater than in the light series, then the omission to which I refer above is sufficient to upset it. Since the figures of the average size which Dr. Weinbren gives "may," by his own admission, include whole ulcers, where only a part was treated, I can hardly accept them. In any case, my work has not given me the impression that the worst ulcers, within limits, are necessarily the largest. The rate of healing may be more rapid in large than in small ulcers, and the last stages are often the most intractable.

4. The ambulatory cases receiving irradiation wore no support other than their ordinary bandages, in order that the issue might not be confused by the simultaneous adoption of two lines of treatment. The evidence of the healing which occurs with Unna's paste clearly shows the fallacy involved in attempting to judge the effect of synchronous treatment when the veins are well supported. Dr. Weinbren himself, in the last number of the *British Journal of Actinotherapy* (I quote from memory, as I am away from home), expresses the opinion that the rate of healing under ultra-violet light is to some extent dependent on the use of adjuvant factors. I agree with him. That is what my experience has taught me; but his adjuvant factor is my essential factor.

I am, Sir, yours faithfully,

June 24th, 1928. DORA C. COLEBROOK.

REMOVAL OF THE RIGHT CEREBRAL HEMISPHERE IN MAN.

To the Editor of THE LANCET.

SIR,—In your interesting annotation in THE LANCET of June 30th (p. 1337) it is stated that in Dandy's successful case of removal of the right cerebral hemisphere "hearing remains normal in both ears, a finding which disposes of the assumption that there is cortical representation for hearing in the right temporal lobe." This inference, as I understand it, is not deducible from the facts which really go to support the assumption or, rather evidence, that there is cortical representation on each side for both ears. In support of this I would quote the late Sir Frederick Mott's case of a woman in which a vascular lesion of the left cortical centre led to word-deafness, from which she recovered and got married. She unfortunately sustained a vascular lesion of the right cortical centre and only then became quite deaf. Karl Grabe's pathological investigations on central disturbances of hearing[1] showed that in damage to one cortical centre hearing for speech is only slightly diminished, the diminution being more marked in the ear opposite to the lesion.

---

[1] Zeits. f. Hals-Nas.- u. Ohrenheilk., 1923, vi., 498.

The representation of each cochlea in both cortical centres is unquestionable and indispensable; for if, for instance, the left cortical centre were in connexion with the right ear only we would presumably find ourselves afflicted with word-deafness if this ear were stopped up, which is obviously absurd.

It is, therefore, quite natural that the loss of the right cerebral hemisphere should not involve deafness of either ear. The loss of the *left* hemisphere would no doubt (in a right-handed patient) entail "word-deafness," if only for a time, as in Mott's classical case. I am, Sir, yours faithfully,

London, July 2nd, 1928. JAMES DUNDAS-GRANT.

ACUTE APLASTIC ANÆMIA.

To the Editor of THE LANCET.

SIR,—In referring to the treatment, followed by recovery, of the case of this hitherto rapidly fatal disease recorded in my book, your reviewer (THE LANCET, June 23rd, p. 1285) states that "numerous therapeutic products of one sort and another" were used, and suggests that, therefore, it is impossible to assess the part played by injections of liver substance. This conveys the impression that the treatment was of the "blunderbuss" type. Over a period of 3½ months three treatments were used (if we exclude such medicaments as rhubarb and soda, calomel, and the mild measures directed against the intestinal infection, none of which can have had any effect on blood regeneration). These treatments were hemostyl, liver substance, and vaccines. The stock vaccines were given sporadically to combat complicating catarrhal infections. Diet can be excluded as a factor, since the child was on a dietetic régime supervised from birth and, if anything, the diet was less adequately supplied with vitamin A and fats during the illness than before it—a point dealt with by me in criticising Koessler's views regarding the importance of these substances in blood regeneration. We are left with hemostyl and liver substance as therapeutic measures, and the alternative possibility of spontaneous recovery. This last can be ruled out by the fact that no case of recovery from *acute* aplastic anæmia has been recorded. The two cases quoted from my book by your reviewer were of chronic aplastic anæmia and were introduced to support my argument regarding a liver hormone-organ controlling blood production. One of them could only be traced for 12 months after the reported recovery, and the other (Gibson's case) has not completely recovered, and was still under treatment with an abnormal blood count some months ago. My case is now running about and apparently normal, having had no liver treatment (except for one week in May) since February.

Treatment by hemostyl and by liver substance only overlapped for three days—i.e., from Nov. 5th to 8th. In spite of the reaction in the platelet system during hemostyl treatment, the other marrow-formed elements continued to descend, the polymorphs reaching one of the lowest counts recorded in the literature. After five days of liver treatment regeneration was observed. The total number of the polymorphs was taken as the index of efficacy of the treatment throughout, and their curve closely followed the dosage curve. The reticulocyte count to which others attach so much importance (following the lead of the Americans), was not used, mainly because its value is more qualitative than quantitative, and it cannot therefore be as serviceable a guide to dosage. Throughout the period of liver disturbance the total polymorph count shows a quantitative relationship to the amount of liver substance injected, and was a most valuable guide to dosage. Armed with the convictions tentatively put forward in my book, I have since treated a number of cases of varying degrees of depressed bone-marrow function with injections of liver substance; the results, which will be published later, are most gratifying.

Others have proclaimed the uselessness of liver therapy in aplastic anæmia. The recorded data upon which this misleading pronouncement is based are inadequate and unscientific. Masses of liver by the mouth, even concentrated extracts by the mouth, are a crude form of treatment compared to hypodermic medication. Successive blood counts, unless taken at the same time each day in a particular case, are not a true indication of progress, particularly in children. Counts done by different individuals on the same patient increase the margin of error due to the personal equation and cannot be compared with counts done by a single skilled pathologist; this especially applies to platelet counts. When one contemplates the helplessness of the physician confronted with this dreadful illness a life-saving measure, which at least has the merit of simplicity, is deserving of respect.

I am, Sir, yours faithfully,

Bradford, June 28th, 1928. A. HAYES SMITH.

ENCEPHALO-MYELITIS FOLLOWING VACCINATION.

To the Editor of THE LANCET.

SIR,—In a recent letter in your columns we reported six cases of acute meningo-encephalo-myelitis, with the statement that these cases "differed in many respects from acute epidemic encephalitis and showed a marked clinical similarity to post-vaccinal encephalitis." Prof. Ledingham, writing on June 16th, states that this "would imply that this latter affection possesses a more or less stereotyped symptomatology." We cannot agree that our letter contained such an implication, and we are as familiar as Prof. Ledingham with the variability of the clinical pictures. Our six cases present this variability in a striking manner. Thus we state that "cervical rigidity and Kernig's sign were present in four cases and trismus in one. . . . Aphasia was noted in two cases, quadriplegia in one, hemiparesis in one, and in one the principal signs were those of a myelitis." The variability of our cases, in fact, appeared to us to be a further point of resemblance between them and post-vaccinal encephalitis.

It is a matter of general experience that many diseases present an extremely variable clinical picture. This is notably the case with encephalitis lethargica and with disseminated sclerosis, but this fact does not debar us from regarding them as clinical entities and from speaking of resemblances and differences between them.

We are, Sir, yours faithfully,

DONALD HUNTER.
W. RUSSELL BRAIN.

London Hospital, Whitechapel, E.,
July 2nd, 1928.

GLASGOW HOSPITALS.—On Friday in last week the Prince of Wales attended one of seven performances of a Scottish historical pageant in the grounds of Garscube House, Glasgow, in aid of the building fund of the Incorporated Glasgow Dental Hospital. Many of the characters were impersonated by their descendants. The existing hospital premises have been condemned as "a derelict dwelling-house" and insanitary, with no possibility of making provision for dental research.—The annual report of the Glasgow Royal Hospital for Sick Children states that the number of in-patients has grown from 1089 in 1907 to 7143 in 1927, and the out-patients' attendances from 42,302 to 83,591. In 1907 the ordinary expenditure was £7861; last year it was £38,039. The first part of the programme of enlargement has now been completed, and the provision of better accommodation for the nurses and domestic staff has made two more wards available for patients. Progress will now be made with the new admission block, which will not only provide for a greatly increased number of out-patients but will provide space on the upper floors for nearly 100 patients. A lecturer on biochemistry in relation to infancy and childhood is about to be appointed in the University of Glasgow, and he will be biochemist to the hospital and work in its laboratory. It is also hoped shortly to establish a research lectureship on the pathology of the diseases of infancy and childhood. The endowment of £15,000 for this purpose is being provided by Mr. William G. Gardiner and Sir Frederick Gardiner.

Obituary.

EDGAR MARCH CROOKSHANK, M.B. LOND.,

EMERITUS PROFESSOR OF COMPARATIVE PATHOLOGY AND BACTERIOLOGY, KING'S COLLEGE, LONDON.

WE regret to announce the death of Dr. E. M. Crookshank, which occurred on Sunday last, July 1st, at his country house, Ridge Hill Manor, East Grinstead, in his seventieth year.

Edgar March Crookshank, the son and grandson of soldiers, from school age showed a bent towards natural science. He was educated at King's College School and, proceeding to the hospital, obtained the diploma of M.R.C.S. in 1881, graduating in medicine at the University of London three years later. His career as a student was distinguished, for he gained both exhibitions and scholarships at King's College, while he won the gold medal in anatomy in the examination for the London M.B. Lister arrived in London to take up his appointment at King's College Hospital at the time when Crookshank was completing his training. The Listerian doctrines were practised more rigidly at King's than at any hospital in the metropolis, and Crookshank, one of Lord Lister's dressers, acted as house surgeon to the institution. Owing to this fact, as much as to certain family influence, Crookshank was selected for special duty in the Egyptian Expedition of 1882: he was present at the battle of Tel-el-Kebir, and received the Khedival Star and other decorations.

Following on his experiences of antiseptic surgery in military campaigning, of which he wrote at the time a very sound account, Crookshank decided to make the study of bacteriology his professional career. He proceeded to Paris, where Pasteur, who had already made his famous studies on fermentation, was at work on the problems of rabies, and welcomed the pupil of Lister. Thence he went to Berlin, and studied under Koch, at that time Director of the Institute of Health, and engaged in perfecting his original discoveries in relation to tuberculosis. The result was the publication by Crookshank, in 1886, of a "Manual of Bacteriology" which met with a good reception on its appearance, and secured for its writer the professorship of bacteriology at King's College. Here he founded the laboratory for human and veterinary pathology and did much educational work in connexion with these subjects. He wrote largely and taught energetically, and showed considerable independence of attitude. For example, with regard to vaccination, he followed the lines laid down by that great historian of epidemiology, Charles Creighton, but he attempted also to find grounds of his own for dissent from much accepted teaching. In many places his criticisms of popular conceptions were no doubt sound, and this would to-day be admitted, but he was not able to make converts through his own reasoning to the views which he proposed to substitute. He retired from active work at King's while still a young man, and it is over 30 years since the fourth and last edition of his text-book of bacteriology appeared. But by that time the work was no longer up to date, in spite of reconstruction, revision, and enlargement. In its day, however, it was a valuable contribution to the literature of what was still a new subject; it was inclusive—ambitiously so; it was well illustrated, both by original illustrations and by loans from the best sources; it was furnished with appendices, in which practical instructions were given as to the fitting-up of the laboratory; and it had a bibliography through which readers could obtain a real introduction to French and German literature.

On his resignation of his post as active professor in 1889, he was given Emeritus rank and elected a Fellow of King's College; but he carried into retirement a keen interest in medical and especially veterinary problems, while his interest in local administration was widely manifested. In 1891 he was appointed J.P. for Sussex, and became at once an active member of the Bench, taking a prominent part in the public life of the district, while he stood for the East Grinstead Parliamentary Division of the County as a Unionist. He took, further, advantage of all opportunities for travel always combining his sporting proclivities—and he was an accomplished hunter of big game—with careful investigations into the various social problems of the places which he visited, and these included South Africa, Australia, Canada, and the West Indies. Thus he familiarised himself with the productive powers of most of the countries under our Colonial administration. All these experiences confirmed him in his deep interest in veterinary surgery, manifested early in the circumstances of the founding of the bacteriological laboratory at King's College. He was for nearly 40 years one of the governors of the Royal Veterinary College, and presided at different times over the committee of management of the Research Institute and of the General Purposes Committee, and took a prominent part in the appeal for rebuilding the present College in Camden Town.

Prof. Crookshank married, in 1885, Harriet, only daughter of Thomas Colfax, J.P., of Bridport, by whom he had two sons and three daughters.

HENRY HANDFORD, M.D. EDIN., F.R.C.P. LOND., D.P.H.

Dr. Henry Handford, who died on June 24th at the age of 73, long played an important part in the public life of Nottingham and its county, first as clinician and later as administrator. A son of Dr. Thomas Handford, who practised at Atherstone, in Warwickshire, he was educated at the University of Edinburgh, where he proved a brilliant student, winning University medals in physiology, pathology, medicine, clinical surgery, midwifery, and other subjects. After graduating as M.B., C.M. with honours in 1878, he took up an appointment as medical tutor at Queen's College, Birmingham. It was not long, however, before he decided to settle in Nottingham, and as physician to the General Infirmary he soon won a high reputation for wide learning. Though he read extensively, his knowledge was chiefly his own, acquired by diligent observation and exact examination of his patients. The signs and symptoms which they presented were always interpreted as far as possible in the light of the most recent pathological knowledge available, and Handford was himself a careful student of pathology. As an illustration of his methodical research we may recall a demonstration before the Nottingham Medical Society in 1884, when he showed numerous pure cultures of pathogenic organisms, and in the following year when he showed microscopical preparations of *Bilharzia hæmatobia* and sections from cases of choreic insanity, myelitis, actinomycosis and supposed malignant pustule. This list is evidence of the wide range of his interests, and their catholicity is further shown by the titles of papers read before the Pathological and Clinical Societies of London, of which he was a keen member. In 1904 he described a case of heart-block and demonstrated the causative lesion, a gumma in the bundle of His; and many papers in medical journals bore witness to his special interest in cardiology. In 1899 the value of his contributions was recognised by his election as a Fellow of the Royal College of Physicians of London, of which he had become a Member in 1885. Seven years later he resigned his post of honorary physician to the General Hospital on being appointed medical officer of health for the county. In this new work he displayed the same thoroughness, conscientiousness, and courtesy to those with whom he worked, but his friends could not but regret the loss to clinical medicine in the city. During his 26 years of office he found much to do for the welfare of the county, and also served a term of office as president of the Midland Branch of the Society of Medical Officers of

Health. "Those who knew him well," writes a colleague, "admired him equally for his excellence as physician and for his qualities as a man. No one could be more kind and courteous than he was at all times and under all circumstances: there was about him a sort of refined dignity of bearing which compelled respect. A love of literature and music and a great hatred of any approach toward untruthfulness completed the picture of the truly cultured gentleman."

Dr. Handford married a daughter of the first Lord Belper, and she survives him. His two sons were killed on Jan. 1st, 1916, at the Hohenzollern Redoubt.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

DUTY ON SCIENTIFIC FILMS.

On Tuesday, July 3rd, the House of Commons went into Committee on the Finance Bill, Mr. J. F. **HOPE**, Chairman of Committees, in the chair.

Captain **FRASER** moved a new clause to exempt from duty films recording scientific investigations or research which are imported into Great Britain or Northern Ireland when the Commons were satisfied that the films would not be sold or hired or publicly exhibited for profit. He said that the man who had carried out researches with a microscope, or in other directions of a scientific, and particularly of a medical-scientific kind, now found it possible, through the technique which had been developed, to record those researches and investigations upon a film instead of upon paper. The free interchange of the results of these investigations was something which no taxation should be allowed to impede.

Dr. **DRUMMOND SHIELS** seconded the new clause. He said that, even in the few years since 1925, the importance of these scientific films had considerably increased. Many of them had originated in America, Germany, and other countries, and they had proved most valuable for teaching and scientific purposes. There ought to be free trade in all that appertained to science and research. The only possible objection he could see was that of administration, but it should be possible for the scientific bodies to which such films would be consigned to give a certificate which would make it possible to work this exemption without causing much administrative difficulty. He hoped that the Chancellor of the Exchequer would receive the proposal in a sympathetic spirit.

Mr. A. M. **SAMUEL** (*Financial Secretary to the Treasury*) said that this clause had received the most careful consideration, with a desire, if possible, to give effect to it. It had been found, however, that, in these days of popular science, it would be impossible for the Revenue authorities to distinguish the scientific films from those which could be shown in the ordinary way, and to be sure that the former were not subsequently shown in picture-houses.

Captain **FRASER** assured the Chancellor of the Exchequer that the films to which the clause referred were only of scientific interest and were in no sense of the word "popular."

Mr. **CHURCHILL** said that while he could give no undertaking in the matter, he would see that the facts were examined again. Those responsible for making that inquiry would receive any further evidence that Captain Fraser might bring forward.

The proposed clause was then withdrawn.

HOUSE OF LORDS.

THURSDAY, JUNE 28TH.

Dogs Act (Amendment) Bill.

The Earl of **CRANBROOK** moved the second reading of the Dogs Act (Amendment) Bill which has passed through the Commons. The measure, he explained, extended the liability of the owner of a dog which did injury to poultry. The Bill also dealt with the delivery of stray dogs to the police.

Viscount **BERTIE** of **THAME** pointed out that whereas under the principal Act no dogs could be sold for vivisection, found dogs under this Bill were not so protected. In Committee he would move an amendment to bring the Bill into line with the present law in that respect.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 27th.

Small-pox in England and Wales.

Mr. **SHEPHERD** asked the Minister of Health the number of cases of small-pox reported for England and Wales for the latest week available; and the number of cases discovered amongst casuals during any convenient period.—Mr. **CHAMBERLAIN** replied: The provisional number of notifications of cases of small-pox in England and Wales for the week ended June 23rd last was 230. I have no precise information as regards the latter part of the question, but during the period Jan. 24th to June 25th, 1928, 124 cases of small-pox have been reported among casuals.

Health Insurance Benefits and Outdoor Relief.

Mr. **LANSBURY** asked the Minister of Health what instructions, if any, he had issued to his inspectors and to public auditors in connexion with poor-law relief to persons in receipt of national health insurance benefit; and whether he was aware that his officers and certain auditors were forcing boards of guardians to take into account health insurance benefits when assessing outdoor relief, despite the fact that the Insurance Acts expressly provided that boards of guardians should not take health insurance payments into account when assessing the need of applicants for poor-law assistance.—Sir **KINGSLEY WOOD** replied: My right hon. friend has given no instructions of the kind suggested in the first part of the question. The answer to the second part is in the negative. I would, however, remind the hon. Member that boards of guardians are only precluded from taking into account health insurance benefits up to 7s. 6*d*. a week.

Inspector of Medical Supplies.

Mr. **JOHN PALIN** asked the Secretary of State for War whether the inspector of medical supplies employed at the War Office was a qualified pharmacist; and whether it was part of the duties of the inspector of medical supplies employed at the War Office to pay periodical visits to the medical store depôts for the purpose of inspecting medical supplies and of ascertaining whether due care was being exercised in respect of the storage of such medical supplies.—Sir L. **WORTHINGTON-EVANS** replied: The inspector is qualified; there is only one Army medical store depôt; it is not part of his duty to inspect it.

Mr. **PALIN** also asked the Secretary of State for War whether the advice of the inspector of medical supplies had been taken as to what medicinal preparations used by the Army could be conveniently and economically prepared in the dispensing laboratories of Army hospitals.—Sir L. **WORTHINGTON-EVANS** replied: Yes, sir.

Silicosis and Workmen's Compensation.

Mr. **WILLIAM HIRST** asked the Home Secretary the total number of claims at the latest available date under the Workmen's Compensation Act, in connexion with the silicosis scheme, by July, 1927, and the number as affecting Birmingham and Sheffield respectively.—Sir **WILLIAM JOYNSON-HICKS** replied: I presume the hon. Member refers to the scheme for the metal grinding industries which came into operation on July 1st last year. I regret that I am unable at present to give any figures, but information as to the number of cases in which compensation was paid under this scheme during the six months, July to December, 1927, is being collected and will be available later.

THURSDAY, JUNE 28TH.

Allowances to Mentally Deficient Orphans.

Sir **RICHARD LUCE** asked the Minister of Pensions if he would consider the possibility of extending benefit under the Pensions Act to the orphan children of pensioners who were mentally or physically deficient after they reached the age of 21.—Major **TRYON** replied: I have no authority under the Royal Warrants to continue allowances, which normally cease at the age of 16, beyond the age of 21. I have, however, taken, and am taking, measures within my powers, and without encroaching on the obligations of local education and health authorities in the matter, to coöperate with other agencies in securing such suitable treatment or training of the children before they reach the age of 21 as will enable them as far as possible to contribute to their own support.

Medical Inspection of Casuals.

Mr. **SHEPHERD** asked the Minister of Health when the order for the medical inspection of casuals expired and whether it was his intention to extend it.—Mr. **CHAMBERLAIN** replied: I am extending the present direction on this subject, which expires at the end of this month, to the end of September next.

Welsh Board of Health.

Mr. John Williams asked the Minister of Health whether he could make any statement to the House on the future constitution of the Welsh Board of Health; whether it was proposed permanently to reduce that body to three; and what the number of the body was when originally set up.—Mr. Chamberlain replied: The Welsh Board of Health consisted of three members when it was originally constituted. At a later date the administrative officer for public health became an ex-officio member of the board. With regard to the first and second parts of the question, I would refer the hon. Member to the answer given on June 25th.

Mr. John asked the Minister of Health who was the present Member for Wales on the National Health Insurance Joint Committee; who would be the member in future; and whether Mr. John Rowland, a member of the Welsh Board of Health, was to act as deputy for him.—Mr. Chamberlain replied: The present member of the National Health Insurance Joint Committee appointed by me under Section 88 of the National Health Insurance Act, 1924, as "a person having special knowledge and experience of National Health insurance in Wales," is the hon. Member for Monmouth, and I do not propose to make any change. I have appointed Mr. John Rowland to succeed Sir Thomas Hughes as deputy to the hon. Member for Monmouth at meetings of the Committee at which the hon. Member is unable to be present.

Captain Arthur Evans asked the Minister of Health if he would consider the advisability of appointing one of the present reduced Welsh Board of Health a member of the joint consultative committee of the United Kingdom, instead of appointing a deputy for a representative whose official connexion with the Welsh Board of Health has now terminated.—Mr. Chamberlain replied: My hon. friend appears to be under some misapprehension. The hon. Member for Monmouth, who is and has for some years been the Welsh representative on the National Health Insurance Joint Committee, is not in any way officially connected with the Welsh Board of Health. The retiring chairman of the Welsh Board of Health was appointed to act as deputy to the hon. Member for Monmouth at meetings of the Committee at which the hon. Member was unable to attend, and I have now appointed a member of the Welsh Board of Health to act in the same capacity.

Captain Evans also asked the Minister of Health, seeing that the actual saving effected by not appointing one of the present reduced Welsh Board of Health as chairman was approximately £300 per annum, and that the status and influence of such an important board must be detrimentally affected by the exclusion of a chairman, whether he would appoint one of their present number chairman.—Mr. Chamberlain replied: The status and functions of the Welsh Board of Health are not, in my view, affected by the decision not to appoint a chairman. The bulk of the work of the board is satisfactorily done by the members of the board in their individual capacity, and meetings of the board are but rarely held. The answer to the last part of the question is in the negative.

Unclaimed Bodies for Anatomical Examination.

Mr. Kelly asked the Minister of Health the reason for the request made by his department that unclaimed bodies of deceased patients in the Park Prewet and Brookwood Asylums, and other mental institutions under the Farnham Union, should be handed over to the University of Oxford for anatomical examination.—Mr. Chamberlain replied: The request to which the hon. Member refers has been made to these and other similar institutions in order to assist in the provision, under proper safeguards, of unclaimed bodies for anatomical examination, which is indispensable to medical education.

MONDAY, JULY 2ND.

Biochemical Research.

Miss Wilkinson asked the President of the Board of Trade what aid, financial or otherwise, the Government was giving to promote research into the practical application to industry of the science of biochemistry.—Mr. H. G. Williams (Parliamentary Secretary to the Board of Trade) replied: A considerable amount of biochemical research is conducted by the Department of Scientific and Industrial Research, particularly in relation to its investigations on the preservation and transport of foodstuffs. The Department also makes grants to a number of coöperative research associations, organised by various industries to investigate their own special problems, whose work is partly of a biochemical nature. As this work is closely linked up with other work not directly biochemical in nature, it is impossible to estimate its cost separately.

Refuse Burning in Louth and Public Health.

Lieut.-Colonel Heneage asked the Minister of Health if he had received a resolution signed by inhabitants of Louth calling attention to the burning refuse pit in the town, which was so situated that odours and smoke were causing danger to health and annoyance to inhabitants; and what reply he had returned.—Sir Kingsley Wood replied: My right hon. friend has received a petition in reference to this matter, and is communicating with the town council.

The Rating of Voluntary Hospitals.

Captain Cazalet asked the Minister of Health whether he was aware of the inconsistencies prevalent to-day throughout the country in regard to the rating of voluntary hospitals; that in Devon the rating assessment committees had resolved that voluntary hospitals in that county should be rated at 7*s.* 6*d.* per bed, including nurses' beds, while in Wiltshire the rating and assessment committees had adopted the basis of £5 per head additional to nurses' beds; and whether he could give to the House the assurance that such inequalities would be removed under the new Valuation and Rating Act.—Sir Kingsley Wood replied: The Central Valuation Committee has reported the existence of considerable diversity of practice in the assessment of voluntary hospitals. My right hon. friend has circulated the Committee's recommendations on this matter to the local authorities concerned, but he is not empowered to interfere with their discretion in the assessment of any class of hereditament. I may add that the matter is not germane to the Government's proposals for giving relief from rating burdens to agriculture and industry.

Spitting in Public Places.

Major Colfox asked the Minister of Health whether he would, in the interests of public health, introduce legislation to prohibit the practice of spitting in public places.—Sir W. Joynson-Hicks replied: No fresh legislation is required. The matter is one which can be dealt with by the local authorities by means of good rule by-laws under the Municipal Corporations Act and Local Government Act. By-laws on the subject are in force in a number of places.

Destruction of Lost or Strayed Dogs.

Sir Robert Gower asked the Home Secretary whether his inspectors' reports showed that adequate accommodation existed at all police stations for the reception of lost and strayed dogs; and what methods were adopted by the police for the humane destruction of lost or strayed dogs which were not claimed by their owners.—Sir W. Joynson-Hicks replied: I have no information as to the arrangements outside London, but in the Metropolitan Police District the accommodation is adequate, and it is a condition required of the contractors that the dogs handed over to them which are not claimed should be destroyed in such manner as to cause as little pain as possible.

TUESDAY, JULY 3RD.

Medical Services in Scotland.

Sir Archibald Sinclair asked the Secretary of State for Scotland whether his attention had been drawn to the statement in the Report of the Scottish Board of Health that the gap was widening between the standard of medical services in the Highlands and that in the Lowlands; and what provision was being made for the maintenance and improvement of the Highlands and Islands medical service during the current year.—Sir J. Gilmour replied: The statement referred to expresses the view of the Consultative Council on Highlands and Islands, whose report I have seen and am now considering. As regards the second part of the question, the money available in the Highlands and Islands (Medical Service) Fund is sufficient to maintain the medical services on their present scale during the current year. It is anticipated, however, that the fund will be exhausted by the middle of next financial year, before which time the question of what further financial provision should be made will be fully considered in the light of the whole circumstances of the case.

Sir A. Sinclair asked if provision would be made in the meantime for catching up the leeway as well as for maintaining these services at the lower level to which they had fallen.

Sir J. Gilmour said that the provision for this year had been made and would be carried out to the full.

THE ASTHMA RESEARCH COUNCIL.—A part-time research scholarship is being founded to investigate the various physical treatments of asthma. The selected candidate will be required to visit Mont Dore and other continental resorts for the treatment of asthma prior to taking up the work in London, and preference will be given to one who already holds a professional post. An advertisement in this issue of THE LANCET sets out the conditions of the appointment. Dr. E. A. Cockayne and Colonel F. E. Fremantle, M.P., have joined the Medical Advisory Committee of the Council.

Medical News.

UNIVERSITY OF OXFORD.—At a Congregation held on June 28th the following degrees were conferred:—

D.M.—A. A. F. Peel and F. E. Fremantle.
B.M.—F. G. Parker.

Dr. John Farquhar Fulton has been elected to a research fellowship in natural science at Magdalen College. Dr. Fulton came to Magdalen as a Rhodes Scholar in 1921. He obtained a first class in the final honour school of physiology in 1923, and subsequently the degree of D.Phil. by research. He returned to Harvard, and since completing his courses for the D.M. degree of that University has been working in Dr. Harvey Cushing's clinic. He proposes to carry on research in physiology and to write on the history of physiology and the bibliography of the works of Robert Boyle.

UNIVERSITY OF BIRMINGHAM.—At recent examinations the following candidates were successful:—

M.D.

J. F. Brailsford and F. W. M. Lamb.

FINAL EXAMINATION FOR M.B., CH.B.

Second-class Honours.—G. H. Knight,* and A. B. Taylor.†
* Distinction in Medicine and Surgery.
† *Distinction in Medicine and Midwifery.*

Pass.—Mohamed Badr-El-Din, Charles Davies, I. K. Donovan, R. E. Johnson, C. E. Perry, F. R. Roberts,‡ M. C. Rosser, M. D. Sandoz, J. G. Stooke, and Nubar Yacoubian.
‡ *Distinction in Midwifery and Diseases of Women.*

FINAL EXAMINATION FOR B.D.S.

Class I.—A. T. Wynne.

FINAL EXAMINATION FOR DIPLOMA IN DENTAL SURGERY.

F. W. Hanlan, W. F. Hinds, and E. E. Newitt.

UNIVERSITY OF DURHAM.—At Convocations on June 26th and 27th the following degrees, diplomas, and licences were conferred:—

M.D.—Katherine M. Cellan-Jones, Margaret B. Herbst, I. M. McLachlan, T. H. Meek, P. J. O'Connell, L. G. Pearson, C. E. Reindorf, L. F. Richmond, T. W. Shaw, F. E. Stabler, and M. M. Suzman.
M.D. (for Practitioners of 15 Years' Standing).—Harold Balme.
M.S.—W. P. T. Watts.
M.B., B.S.—H. M. Brown, D. S. Buchanan, W. C. E. Diamond, M. A. Gaffar, Coley Goldstein, J. C. V. Hindhaugh, C. F. Ind, S. W. Smith, J. M. Tait, and H. G. Ungley.
B.S.—Ibrahim Girgis and L. G. Pearson.
B.Hy. and D.P.H.—T. L. J. Coxon, E. F. D. Dawson-Walker, and J. W. Hunter.
L.D.S.—Margaret I. Lamb, R. R. Maclean, C. E. Shafto, and G. S. Yeoman.

UNIVERSITY OF SHEFFIELD.—At recent examinations the following candidates were successful:—

M.B., Ch.B.—K. J. G. Milne,* G. B. Thomas,* W. Alcock, R. D. Dewar, T. E. Gumpert, T. K. Owen, W. A. Timperley, and Joan J. J. Wallace.
* With second-class honours.

UNIVERSITY OF GLASGOW.—At a graduation ceremony on June 29th the following degrees were conferred:—

M.D.—*Mary P. McCunn, Robert Armstrong, and David Henderson.
* With commendation.

The History of Medicine Prize was awarded to Dr. William James Rutherfurd for an essay entitled A Cock to Æsculapius.

UNIVERSITY OF ST. ANDREWS.—At a graduation ceremony on June 28th the honorary degree of LL.D. was conferred, among others, upon Dr. E. P. Cathcart, Gardiner Professor of Physiological Chemistry in the University of Glasgow; and Dr. William Darrach, Professor of Surgery in Columbia University, New York.

UNIVERSITY OF DUBLIN.—At a meeting of the Senate on June 30th the honorary degree of Master of Surgery was conferred on Sir John Bland-Sutton; the honorary degree of Doctor of Science on Dr. George Linius Streeter, director of the Department of Embryology in the Carnegie Institute, Baltimore, U.S.A.; and the honorary degree of Master of Arts on Miss Margaret Huxley, an Overseer of Trained Nurses in Ireland. Of Sir John Bland-Sutton, the Public Orator, Sir Robert Tate, spoke as famous alike as operative surgeon, teacher, scientific investigator, and learned archæologist. Miss Huxley, generally regarded as the leading representative of nursing in Ireland, the Public Orator described as "feminam strenuam, certam, optimam" in reference to her magnificent work as matron of Sir Patrick Dun's Hospital. In the evening Miss Huxley was entertained at dinner by a large company of hospital matrons.

HUNTERIAN SOCIETY.—Dr. Arthur Westerman has been elected president of this Society for the coming year. The honorary secretaries are Mr. W. E. Tanner and Dr. D. C. Norris.

EPSOM COLLEGE: ANNUAL GENERAL MEETING OF GOVERNORS.—Dr. Raymond Crawfurd presided at the seventy-fifth annual general meeting of the Governors of Epsom College on Friday, June 29th, 1928, at the office, 49, Bedford-square, W.C., when there was a good attendance. The following is a list of the successful candidates for pension and foundation scholarships at the elections, together with the number of votes gained in each case. Dr. Raymond Crawfurd, Dr. J. Walter Carr, and Dr. Seymour Taylor were the scrutineers. Hadlow Pensioners: Dr. James S. Robertson, 4157; Mrs. Gertrude Middlemist, 3326; Mrs. Elizabeth Christian, 2485; and Mrs. Mary G. S. Kenny, 2086. Ordinary Pensioners: Mrs. Ellen M. Blake, 2057; Dr. Lambert Houghton, 2012; Mrs. Ida M. S. Style, 1672; and Dr. Vincent O. Taylor, 1634. Pugh Pensioner: Mrs. Mary K. Ingledew, 1481. *Brodie Sewell Annuities*: Miss Ella M. Leney, 2631; and Miss Elizabeth E. B. D'Olier, 1793. *Foundation Scholars*: Alfred G. Stansfeld, 17,657; Geoffrey G. Wallis, 13,079; John R. Copeland, 11,042; John A. K. Holburn, 10,757; John Watson, 10,496; Antony L. Haynes, 10,427; Louis C. Dillon, 8051; and Eric J. Holborow, 6531.

Dr. F. W. Collinson and Dr. R. W. Innes Smith were elected vice-presidents of the College in recognition of their valued services, each having collected a sum of over £1000 as honorary local secretary.

In proposing the adoption of the report for the past year, the Chairman referred to the progress of the fund opened for the provision of a new sanatorium, outline plans for which, together with full particulars as to the accommodation, were given in THE LANCET of Dec. 3rd last. Dr. Crawfurd pointed out that if two sums of £5000 were to be received, the Council would be in a position to put the work in hand, as the total collected to date amounted to close upon £5000. The College would benefit in another direction by the provision of this building, as the old sanatorium could be easily adapted for the admission of about 40 more boarders, and the enlargement of the school in this way would result in many economies. Furthermore, the increased income would enable the Council to improve the salaries paid to the masters.

BRITISH PATHOLOGISTS ASSOCIATION.—The second summer meeting of this association was held in the Pathological Department of the Royal Infirmary, Chester, on Saturday, June 30th, Dr. W. H. Grace, pathologist to the hospital, being in the chair. The meeting was devoted to the discussion of the methods used in the examination of the blood. Procedures were described and demonstrated as follows: by Dr. J. G. Greenfield, the making and staining of blood-films, the differential count of the white cells, the counting of the red and white cells, the estimation of hæmoglobin by the Hellige method, and the reticulocyte count; by Dr. A. Renshaw, the examination of the blood for parasites and the presence of organisms; by Dr. S. C. Dyke, the platelet count, the grouping and matching of bloods, and the estimation in the blood of cholesterol, bilirubin, and inorganic phosphates; by Dr. Grace, the estimation of the blood-sugar by the Folin-Wu method; by Dr. A. G. Shera, the estimation of the blood-sugar by MacLean's method and of the blood-urea by Kennaway's method; by Dr. A. F. S. Sladden, the estimation of the blood-urea by a modification of MacLean's method; and by Dr. W. E. Carnegie Dickson, the estimation of the serum calcium. The members of the staff of the Chester Royal Infirmary entertained the members of the association at dinner in the evening.

LONDON HOSPITAL PRIZE-GIVING.—The distribution of prizes on June 29th opened with a report on the Medical College by the Dean, Prof. William Wright. After referring to the knighthoods recently conferred on two old London Hospital men, Dr. J. A. Hosker, of Bournemouth, and Mr. H. S. Newland, of Adelaide, he mentioned that Sir Henry Head had been awarded the Moxon Medal of the Royal Society, and that Prof. Major Greenwood had been elected F.R.S. The hospital had lost, by resignation, the services of Dr. Lewis Smith and Sir Hugh Rigby, whose professional lives had been uninterruptedly linked with it. The vacancies thus left in the hospital staff had been filled by Dr. Russell Brain and Mr. Hugh Cairns, whilst Mr. G. V. Stephenson had been appointed demonstrator of anatomy in the College. Prof. Wright then spoke of the deaths which had occurred during the year, including those of Dr. C. W. Daniels, Mr. A. D. Dinnis, Dr. Nelson Younger, Mr. L. R. Fifield, and Dr. A. Lister. Another loss was sustained by the death of Mr. W. Douro Hoare, chairman of the College Board from 1898 to 1921, to whom the College owed much. A lectureship in ophthalmology, said Prof. Wright in conclusion, had been established with a legacy of £1000 from Mr. Warren Tay.

The Chairman, Lieut.-Colonel W. M. Pryor, then introduced Sir Samuel Hoare, Secretary of State for Air, who came, he said, as the head of a family which had been intimately associated with the hospital and College for many years.—Sir Samuel presented the prizes and honorary certificates of merit awarded to students of the Medical College and Dental School. As the world grew more complicated, he said, it was more and more difficult for men in one profession to keep in touch with men in another. He came, therefore, to learn something about the London Hospital and to tell something about the development of aviation, and he was glad to think that there was already a link between the two in the person of Group-Captain Martin Flack, one of his senior medical advisers. The tests of fitness for flying had been developed by practice rather than theory. The investigators had started by taking their hundred best pilots and analysing their qualities. He wondered whether this method could be applied in the medical profession or in politics. In the profession of collecting money it would be unnecessary to look out for 100 beggars; they could simply analyse the qualities of Lord Knutsford. The medical profession, continued Sir Samuel, was trying to raise the standard of the world's health. He was engaged in attempts to improve its communications. These were the two first needs of the world to-day, especially in the less-developed parts of the British Empire. In recent military operations in the Kurdistan mountains there was a very serious outbreak of dysentery among the troops, but it proved possible, with aeroplanes, to remove the 200 sick to Bagdad, so that they all recovered.

A vote of thanks to Sir Samuel Hoare was proposed by Lord Knutsford, and seconded by Dr. Robert Hutchison.

CARLISLE FEVER HOSPITAL.—As the result of the recent inquiry, described in THE LANCET of June 16th (p. 1239), the Charity Commissioners have agreed to the transference of the Carlisle Fever Hospital to the corporation of the city. The claim of the city council to the control of the hospital was based upon the fact that, in conjunction with the rural district council, it had for many years past chiefly maintained the institution. The claim was opposed by the governing body of the Cumberland Infirmary, which is only 150 yards from the fever hospital, on the grounds that, in the event of further extension becoming necessary, the site of the fever hospital would provide the means of enlargement and that an institution for the treatment of cases of infectious disease is in its wrong place amid a considerable population.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, July 9th to [illegible] 14th.—ST. JOHN'S HOSPITAL, [illegible] road, W. S[illegible] 262, Uxbridge- [illegible] ALL SAINTS [illegible] .30 P.M. on Tues.—Special [illegible] Bridge-road, S.W. W[illegible] 30 P.M. on Wed.—ROYAL W[illegible] HOSPITAL, Broad-street. ab[illegible] at 3 P.M. on Thurs. The [illegible] HOSPITAL, City-road, E.C.—One week's special course in proctology. Operations, demonstrations, and lectures.—PRINCE OF WALES'S HOSPITAL, Tottenham, N. Two weeks' special course in medicine, surgery, and the allied specialties. Further particulars from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, July 9th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

THURSDAY, July 12th.—4 P.M., Dr. Hector C. Cameron: Demonstration of Children's Ailments.

Appointments.

BRICKWELL, F., M.B. Lond., M.R.C.S., has been appointed Medical Officer, Slough and Stoke Poges Districts.

CONNAN, D. M., M.B., B.S. Lond., D.P.H., Medical Officer of Health for Bermondsey.

Manchester Royal Infirmary: TAYLOR, B. A., L.R.C.P. Lond., M.R.C.S., House Surgeon to the Special Departments; NUGENT, Miss E. A., L.R.C.P. Lond., M.R.C.S., Junior Assistant House Surgeon (Central Branch); SOMERFORD, A. R., M.B., Ch.B. Manch., Assistant Medical Officer, Out-Patient Department; STOKOE, Miss L., M.B., Ch.B. Manch., Clinical Assistant, Medical Out-Patient Department; ANDERSON, Miss J., L.R.C.P. Lond., M.R.C.S., Clinical Assistant, Surgical Out-Patient Department; PEACH, Mrs. E. M., M.D. Manch., Assistant Medical Officer, Dermatological Department; SCOTSON, F. H., F.R.C.S. Eng., reappointed Resident Surgical Officer; GRAY, E. D., M.A., M.B., Ch.B. Aberd., reappointed Junior Assistant Medical Officer, Radiological Department; SMIRK, F. H., M.D. Manch., reappointed Medical Registrar; LAMBERT, V. F., F.R.C.S. Edin., Assistant Surgical Officer, Aural Department.

Queen Charlotte's Maternity Hospital: LOWRY, H. C., M.B., B.Ch., B.A.O. Belf., F.R.C.S. Edin., Senior Resident Medical Officer; and HEGGS, G. B. M., M.R.C.S., L.R.C.P. Lond., Assistant Resident Medical Officer.

Salford Royal Hospital: APPLETON, F., M.B., Ch.B. Manch., House Surgeon attached to the Orthopædic Department; BOLAND, C. R., M.B., Ch.B., B.A.O., attached to the Genito-Urinary Department; and COCHRANE, H. L., M.B., Ch.B., attached to the Special Departments.

Certifying Surgeons under the Factory and Workshop Acts: JORDAN, G. R. L., M.B., B.Ch. Dub. (Halstead, Essex); and WILLIAMS, J. W., L.R.C.P. Lond., M.R.C.S., L.M.S.S.A. (Penarth, Glam.).

Vacancies.

For further information refer to the advertisement columns.

Association of Surgeons of Gt. Britain and Ireland, 17, Wimpole-street, W.—Surgical Scholarship. £350.

Asthma Research Council, London Clinic, Ranelagh-road, S.W.—Half-time Research Scholar. £300.

Barnsley, Beckett Hospital and Dispensary.—H.P. £140.

Bath, Royal United Hospital.—Asst. H.S. £100.

Birkenhead General Hospital.—Cas. H.S. £100.

Birmingham, Queen's Hospital.—Med. Reg. Also 3 Res. Surg. Officers. £200 and £100 respectively.

Brighton, Royal Sussex County Hospital.—Hon. Dermatological Clinical Asst.

Bury Infirmary.—Third H.S. At rate of £150.

Cambridge, Addenbrooke's Hospital.—Resident Anæs. At the rate of £180.

Central London Ophthalmic Hospital, Judd-street, St. Pancras. W.C.—Jun. H.S. £50. Also Pathologist. £75.

Chichester, Graylingwell Mental Hospital.—Third Asst. M.O. £350.

Coventry, Coventry and Warwickshire Hospital.—Res. H.P. £125.

Eastcote, Middlesex, St. Vincent's Orthopædic Hospital.—Res. M.O. At rate of £150.

East London Hospital for Children, &c., Shadwell, E.—Res. M.O. £200.

Exeter, Royal Devon and Exeter Hospital.—Hon. Asst. P.

Exminster, Devon Mental Hospital.—Jun. Asst. M.O. £300.

Gordon Hospital for Rectal Diseases, Vauxhall Bridge-road, S.W.—Res. H.S. £75.

Harefield, Middx., County Tuberculosis Sanatorium.—Sen. Asst. Res. M.O. £450.

Herefordshire General Hospital.—H.P. At rate of £100.

Hospital for Consumption and Diseases of Chest, Brompton.—H.P. £50.

Kimberley Hospital, South Africa.—Radiologist-Jun. H.S. £750.

Lahore, Mayo Hospital.—Anæsthetist, Rs.500/-25-1000/- per mensem.

Leeds City Hospitals.—Med. Supt. £850.

Leeds Public Dispensary.—Sen. Res. M.O. £200. Also Hon. P.

London Female Lock Hospital, 283, Harrow-road, W.—H.S. At rate of £150.

London Jewish Hospital, Stepney Green, E.—Hon. Radiologist.

Maidstone, Kent County Ophthalmic and Aural Hospital.—Aural H.S. At rate of £200.

Manchester, St. Mary's Hospitals.—4 H.S.'s. Each at rate of £50.

Manchester, Salford Royal Hospital.—H.P. At rate of £125.

Marseilles, Queen Alexandra Memorial Hospital.—Res. M.O. At rate of £150.

Mental Hospital, Berrywood.—Locum tenens M.O. £7 7s. pe week.

Miller General Hospital for South-East London, Greenwich-road, S.E.—H.S. £125.

National Hospital, Queen-square, W.C.—Hon. Surg. Asst.

Newark Hospital and Dispensary.—Res. H.S. At rate of £150.

Nottingham, City Mental Hospital.—Jun. Asst. M.O. £350.

Nottingham General Hospital.—Res. Cas. O. At rate of £200.

Nottinghamshire County Council and Mansfield Woodhouse Urban District Council.—Joint M.O. £700.

Portsmouth, Royal Portsmouth Hospital.—Sen. H.S., also Cas. O. At rate of £200 and £100 respectively.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal Army Medical Corps.—Commissions.

Royal College of Surgeons of England.—Election to Court of Examiner, also Election of Examiner in Dental Surgery.

Royal Manchester Children's Hospital, Pendlebury, nr. Manchester. Res. M.O. At rate of £125.

Ryde, Royal Isle of Wight County Hospital.—Res. H.S. £130.

St. Leonards-on-Sea, Buchanan Hospital.—H.S. £150.

St. Mark's Hospital for Cancer, &c., City-road, E.C.—Res. Surg. O. At rate of £150.

St. Mary's Hospital Institute of Pathology and Research, Paddington, W.—Research Studentship. At rate of £200.

St. Mary's Hospital, W.—Dental Surgeon.

St. Pancras School for Mothers, Ampthill-square, N.W.—M.O. 1½ gns. per consultation.

Sheffield, Crimicar Lane Sanatorium.—Asst. Tuberculosis Officer. £450.

Stoke-on-Trent, Longton Hospital.—H.S. £120.

Taunton, Taunton and Somerset Hospital.—Sen. and Jun. House M.O.'s. At rate of £150 and £100 respectively.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. Both at rate of £100.

Wallasey, Victoria Central Hospital.—Jun. H.S. At rate of £100.

West Kent Joint Hospital Board (Infectious Hospitals).—R.M.O. £400 per annum.

West London Hospital, Hammersmith-road, W.—Res. Asst. Surg. £200.

Westminster Hospital Medical School, S.W.—Hon. Lecturer on Tropical Diseases.

Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £100.

Births, Marriages, and Deaths.

BIRTHS.

BISHOP.—On June 28th, at Perryn-road, Acton, W., the wife of Dr. P. F. Bishop, of a son.

CADE.—On June 28th, at Harley-street, W., the wife of Stanford Cade, F.R.C.S., of a daughter.

DONALD.—On June 25th, at a nursing home, Kensington, the wife of Charles Donald, F.R.C.S., of a son.

HUTCHINSON.—On June 29th, at Edwardes-terrace, Kensington, W., the wife of Samuel Hutchinson, M.R.C.S., of a daughter.

MOORE.—On June 28th, the wife of David L. H. Moore, M.B., of a daughter.

STANLEY.—On June 23rd, at rue des Belles Feuilles, Paris, the wife of E. Gerald Stanley, M.D., M.S., F.R.C.S., of a daughter.

MARRIAGES.

EDWARDS—SIMCOCK.—On June 27th, at St. Paul's Church, Heaton Moor, Manchester, Norman L. Edwards, M.B., F.R.C.S., to Margaret Simcock, M.B., eldest daughter of Dr. and Mrs. James Simcock, of Heaton Moor.

STEELE—THOMPSON.—On June 28th, at All Saints', Foots Cray, Kent, Tom Barton Steele, L.D.S. R.C.S. Eng., of Thorneycroft, Christchurch-road, Bournemouth, to Christine Lucy Winifred, only daughter of the late Richard Hanan Thompson, of Fairlight, Chislehurst, and the late Mrs. Thompson, of Upmeads, Dunbar-road, Bournemouth.

DEATHS.

CHETWOOD.—On June 28th, at Christopher-street, E.C., William Chetwood, M.R.C.S., L.R.C.P., aged 82 years.

CROOKSHANK.—On July 1st, suddenly, at Ridge Hill Manor, East Grinstead, Edgar March Crookshank, J.P., M.B., in his 70th year.

HEPWORTH.—On May 20th, at Camberwell, Victoria, Australia, Archibald Francklin Hepworth, L.R.C.P. & S.Edin., aged 61.

READE.—On June 30th, in London, Lt.-Col. William Lloyd Reade, R.A.M.C., aged 70 years.

THISTLE.—On June 26th, at Torquay, Frederick Thomas Thistle, M.D.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

HELPERS IN HYGIENE.*

BY ANDREW BALFOUR, C.B., C.M.G., M.D. EDIN.,

DIRECTOR, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE remarkable changes which the last 25 years have witnessed would have heartened one keen helper in hygiene, the late Sir Benjamin Ward Richardson, a Victorian pioneer and somewhat of a seer in his day. He was the author of a notable book entitled "The Health of Nations," which all those interested in the history of hygienic endeavour should study but, for my present purpose, I would rather cite a passage in his "Vita Medica," that autobiography which he completed in 1896, two hours before he was seized with fatal illness. He has therein a chapter entitled "Efforts towards the Extinction of Disease," where he says: "The best idea, therefore, is that the disturbance or catastrophe called disease—excluding accidents—is not simply to be met by treatment, although that may be necessary and beneficial, but is to be prevented, and that with so much perfection that it shall altogether become extinct, or remain as a mere historical ghost."

Another prophet, though possibly a somewhat optimistic one, who happily is still with us, was the distinguished zoologist, Sir Ray Lankester, when he wrote, a good many years ago, that if we could only apply our present knowledge properly all communicable disease could be stamped out in the short course of 50 years.

Now neither of these men, shrewd, scientific, and well-informed, would have ventured to make such statements unless he had good reason for believing them to be true. They *had* good reason for, within the life-time of each, a veritable revolution had been wrought in our knowledge of the causes and spread of those diseases which can be transmitted from man to man or from some lower animal to man, with or without the aid of an intermediary, in other words, indirectly or directly.

Early Helpers.

It is sometimes forgotten, however, that long before Pasteur revealed the world of microbes and Manson showed how insects play a part in the spread of disease, many helpers in hygiene, by careful observation and sound reasoning, had reached conclusions which, when they translated them into action, yielded very gratifying results. True these men worked in the dark, but they did get hold of some essential facts and so, long before anything was known about the rôle of lice in typhus fever, Lind, the great naval surgeon of the eighteenth century, indicated clearly and correctly what measures would prove effective against that complaint. Similarly, other observers noted the connexion between dirt and diseases of various kinds, notably such intestinal disorders as diarrhœa and dysentery, and preached and practised a hygiene of environment. Long ago in Scotland there was a proverb, "the clartier (that is, the dirtier), the cosier," but the slogan of the health reformers was very rightly "the dirtier, the deadlier," and the deadlier, remember, not only to yourself and your family but to your neighbours and fellow citizens. These early reformers were very largely like voices crying in the wilderness. Few heeded them, save in communities like the Army and Navy where, if the officers commanding were believers, disciplinary measures could be taken, or where pressure could be brought to bear on local authorities and the Government, as when John Howard, shocked and horrified by the condition of the prisons, raised his voice and testified against them.

Mead and Howard, Percival, Ferrier and Currie, the civilians, Lind, Trotter and Blane, the naval surgeons, Pringle, Monro and Jackson, the Army hygienists, lived, laboured, and accomplished much good in a limited way. The country doctor, Jenner, by introducing vaccination, conferred upon suffering humanity one of the greatest boons ever vouchsafed to it and radically altered the situation with respect to small-pox and its victims. It was not, however, until Chadwick, the lawyer, came upon the scene and, with fearless enthusiasm, dogged determination and no little pugnacity, took up the cudgels on behalf of health, that any real and widespread progress was made, apart from what the good Lord Shaftesbury accomplished in the way of factory reform. Then and thereafter, however, a marvellous change ensued, mainly as a result of an organised campaign for cleanliness. What a fight it was, against superstitions and vested interests and supineness and bitter opposition! Although it is true that reform was in the air, that it was a period of quickening and advance in several directions, perhaps the battle might never have been successful had not the country been visited periodically by outbreaks of cholera which swept away hundreds. The scared populace was thankful to listen to those who brought a message of hope, more especially when Dr. John Snow showed that cholera was spread by the intestinal discharges of the sick and indicated polluted water as a source of infection. It was, in great measure, fear which made the people of England loosen their purse strings and provide the wherewithal to obtain pure water, clean dwellings, an efficient removal and disposal of filth and refuse, but, to do these Victorians justice, once they realised they were getting value for their money, they gladly bore the burden and so reaped the reward.

---

* An address delivered under the auspices of the Isle of Man Red Cross Society at the conclusion of Health Week, March 4th, 1928. (Abridged.)

There were, however, other directions in which these early helpers of hygiene exhibited activity. The health of the individual was not altogether neglected though it is true that, for the most part, the individual received attention chiefly because he formed part of a community. It was, in other words, communal, rather than personal hygiene to which the earlier workers devoted themselves. Take, for example, Lind's efforts to get scurvy stamped out of the Navy by the issue to the individual sailor of a ration of lemon juice. Consider how the individual slave benefited from certain efforts affecting his personal welfare, made by Wilberforce and others in their campaign against the appalling conditions of the trade in black ivory.

Until quite recently I fancy that few had any idea that some of the recent developments on which we pride ourselves had their counterparts long ago. Dr. Mabel Buer, of Reading University, has unearthed some interesting facts which show that considerable attention was paid to infant and child welfare in the latter part of the eighteenth and the beginning of the nineteenth century. There was actually a baby clinic in London in 1815, the year of Waterloo.

Now, whence came these more enlightened ideas on the saving of young lives? From a study of the ancient Greeks, that nation of heroes, athletes, and philosophers who certainly were well versed in all matters relating to bodily health? It is unlikely. From the ancient Romans, that race which performed remarkable feats in sanitary engineering and had inherited some of the hygienic wisdom of the Greeks? It is improbable, for the Romans appear to have had little thought for child life.

John Peter Frank.

I cannot help wondering if it was not a legacy from a very remarkable man, a great helper in hygiene, and indeed not only a helper but a leader. So far as I can discover, his name and fame have in this country been wholly forgotten, though upon the Continent, where he lived and worked, they are remembered and they are known also to certain American hygienists. Perhaps in England there has been too great a tendency in matters hygienic to say we are, or were, the people and wisdom remains with us. In other words, knowing that England led the way in public health legislation, English students of the subject are a little apt to imagine that modern hygiene originated in this country and are not disposed to look abroad and see what other nations had done in pre-Chadwickian days. It is true that the English, first of all peoples, placed hygiene on a sound basis, established a definite system of organised sanitary control and enlisted the power of the law in regulating and enforcing public health procedure. Let us, however, remember that when England was sunk in dirt and squalor the cleanliness of the Dutch was proverbial: and let us pay homage to the memory of that leader of whom I spoke, who was no other than John Peter Frank.

His name will not be found in the Encyclopædia Britannica, though quite a respectable space is devoted to another Frank, one Jakob who, of all things on earth, was a Jewish theologian. Yet our Frank was once a name with which to conjure and Napoleon, no mean hygienist himself, tried in vain to obtain his services. He was born at Rotalben, in Bavaria, in 1745, the year before Culloden, when the death-rate in London was 50 per 1000—in 1926 it was 11·6—and life had an uncertainty about it to which it is now a stranger save in the matter of motor vehicles. His father was French. After studying at Heidelberg, Metz, and Strassburg, he gravitated to Göttingen and then to Pavia, eventually becoming Director-General for Sanitation in Lombardy somewhere about 1786. Think of that! In 1795 he was called to Vienna by the Emperor of Austria as consultant for the health of the troops. Thereafter we find him as a Professor at Vilna, then at St. Peterburg, and finally back again in Vienna, where he died, full of years and honours, in 1821.

He must have been a man of courage and humour. When he lay dying there were eight eminent doctors round his bed who had been summoned to attend him. He smiled and said: "This reminds me of the end of a French soldier wounded by eight musket shots at the battle of Wagram." "Morbleu!" said he, dying, "it takes not less than eight bullets to kill a French grenadier."

Frank was a voluminous writer and covered a wide field, but I mention him here because as a hygienist he was far ahead of his period and because he wrote a truly astonishing book entitled "System einer vollstandigen Medicinischen Polizey," This, the first authoritative work dealing with public hygiene, appeared in successive volumes between the years 1779 and 1817.

It dealt with nearly every aspect of hygienic activity, including what we are pleased to regard as modern developments. The author writes on sexual hygiene and maternity and child welfare. He discourses on the education of children. He considers the value of foundling institutes and orphanages, and looks at schools and gymnasia from the public health standpoint. A volume is devoted to the problems of nutrition; food and drink being considered and the importance of moderation stressed. Housing is discussed and public health conditions generally. The question of cemeteries is not forgotten, and there are disquisitions on the healing art and on schools of medicine. The importance of veterinary knowledge and its relations to medicine receive attention, and altogether it is startling to find how Frank anticipated posterity. I can find no record of his great work being translated into English or even into French, but a treatise which he wrote on the method of rearing healthy children was translated into the latter tongue and hence it is conceivable that it was *his* influence which led to the early movements in infant welfare of which we have spoken. In addition to being a great clinician, a man of affairs and an illustrious hygienist, Frank was a dreamer of dreams. He formed the conception of a State guided by public health considerations, a kind of Utopia wherein Hygeia should reign supreme, and where affairs would be conducted for the true and lasting benefit of mankind. It is not surprising that, with his knowledge and acumen, he should have conceived such an idea when, all around him, he saw the misery and wretchedness produced by successive wars and reflected on the welter of intrigue and politics as well as on the endeavours of the proletariat to obtain a place in the sun. Remember, he lived through the days of the French Revolution when, with much that was vile and repellent, there were the germs of great things and indeed in some ways the beginnings of a new world.

Reforms in England.

Whatever may have been Frank's influence on England, there can be no doubt he left his mark on the State medicine of Germany, Scandinavia, and Russia, but he lived, for the most part, in troublous times, and even after his death the Continental nations had not the means to put his precepts generally into practice. The man who followed him was Max von Pettenkofer, but we need not consider his exploits as a helper in hygiene. Rather let us skip the intervening years, including those when Sir John Simon as Dr. Simon and central medical officer to the General Board of Health, was making history, ably assisted by Southwood Smith and others, albeit remembering that Lecky has penned a noble epitaph for these stirring and fruitful times. He wrote: "The great work of sanitary reforms has been, perhaps, the noblest legislative achievement of our age, and if, measured by the suffering it has diminished, has probably done far more for the real happiness of mankind than all the many questions that make and unmake ministries." Its history is set forth in Simon's classic "English Sanitary Institutions." The fight was won but the position had to be maintained; and, furthermore, it soon became evident that the victory, though great, was not complete. In addition it came gradually to be recognised, as Frank had long before envisaged, that new methods of warfare had to be adopted. Let us dwell on these matters for a space. To maintain the position an adequate health organisation was required; and that is why England and Wales have now a Health Ministry, advised by a chief medical officer. Its medical department has separate sections dealing respectively with general health and epidemiology; maternity and child welfare, in which section very fittingly a woman is senior medical officer and the medical officers and inspectors are all women; tuberculosis and venereal disease; the supervision of food-supplies; general practitioner services; sanitary administration in relation to infectious diseases; and Welsh Board of Health to deal with the public health interests of the Principality.

The Work of Public Authorities.

I will comment on some of these immediately. Meanwhile, let us continue the tale and note that other central departments of Government have important health interests and so are helpers in hygiene. The Board of Education with all its responsibilities for the health of school-children and the sanitary condition of schools, the Home Office with its control of the health conditions in factories, mines, and workshops are appropriate examples.

The duties of the medical department of the Health Ministry are, speaking broadly, advisory and supervisory and cover a wide range which you will find listed in that masterly memorandum written by Sir George Newman and entitled "An Outline of the Practice of Preventive Medicine." Every community intent on hygienic progress and, more especially, every backward community striving to amend its ways, should be familiar with its pages. Perhaps the type of the Ministry's activities which will appeal most strongly to an audience of this kind is that whereby an expert is sent from the Ministry to assist the local health officer of a district where either some obscure infectious disease has made its appearance or where some communicable disorder is prevailing as an epidemic and has not yielded to ordinary measures. Medical officers of health greatly appreciate such skilled help, which is also naturally of very definite benefit to the local community and sometimes to the country as a whole. The official local helpers in hygiene are the councils of the areas into which the country is divided. These are the county councils. There is, as you know, a County of London and that county, small in area but packed with people, has its Council, and the Council has its medical and health organisation, a large and most important department charged with most onerous duties.

Outside London the work of the county councils is reinforced by that of the local sanitary authorities, be they urban, rural, or port. There are three types of urban local authorities—namely, the county boroughs, the municipal boroughs, and the urban districts—all acting through their respective councils. The county boroughs are represented by big towns, each with more than 50,000 people; the municipal boroughs are, as a rule, smaller towns; the urban districts, as the name implies, are also townships, and may indeed be very large and important places which happen never to have had conferred upon them by Parliament the title of county boroughs. As a type take Gosport, with its 33,000 people. The rural authorities are the councils of rural districts, which vary a good deal but which all answer to the description of country districts with comparatively small and scattered populations. In these districts, however, there may be small towns or clusters of villages. The state of matters as regards ports varies in different places and may be distinctly specialised. Great ports like London and Liverpool, for example, are under different guidance and control in health matters to the cities whose names they bear.

The Rank and File.

Now the councils of the above-mentioned boroughs and districts are concerned with various aspects of local government—not only with health work—and so, as a rule, at least in places of any size, the care of the people's health is entrusted to a public health committee. Such committees consist for the most part of laymen, and hence must have executive and advisory officers who are experts. These experts are the medical officers of health and in all important places, and I think I may say in all progressive and thoroughly up-to-date places, the medical officers of health are full-time officials. Here, in the great towns, the lesser towns, the villages, the countryside, we find what Newman calls the fighting-line of the never-ending, though usually unobstrusive campaign against inefficiency, disease and death. The medical officers of health and those who assist them and work with them, the sanitary inspectors, health visitors, and nurses, are, like Uriah the Hittite, in the forefront of the battle. So, too, are the executive officers of port health authorities. It is these men and women who are actually up against the forces of death, and remember that under the banner of the arch-destroyer there marches a multitude of legionaries, communicable and non-communicable diseases, ignorance, poverty, vice, drink, gluttony, greed, spite, selfishness, and so forth; it is these workers, the majority, capable and devoted, who are the greatest helpers in hygiene. They are the greatest in the sense that the private soldier, to whom Lord Haig paid tribute, is the greatest fighter. But for their numbers, skill, energy, patience, staunchness and devotion to duty, there would be another tale to tell from that which is told in the columns and obituary notices of the newspapers, in the medical press, and in the reports of the Health Ministry and of the Registrar-General. The commander-in-chief and his staff may plan a campaign. They cannot win it save through the deeds of the rank and file.

What are these deeds in the health campaign? It would take a long time to enumerate them in full, but from what has already been said you have no doubt gathered, if you knew it not previously, that they fall into two chief groups which we may conveniently term environmental and personal. The former are those which the pioneers in this country chiefly practised when they fought and won under the war cry—"Sanitas, sanitatis, omnia sanitas"; the latter embrace the principles which the far-sighted genius of Frank perceived to be essential and others which he did not visualise but which have established themselves throughout the fruitful years when the public health pendulum swung from the old order of things to the new.

The Menace of Dirt.

And here let me remark that, although it cannot be said to have swung too far, for the hygiene of the individual is of paramount importance, yet interest in the new has, I fear, led to some neglect of the old. How otherwise can one explain the filthy condition of some of our streets and highways, the shocking manner in which much of our food is handled, the refuse dumps one encounters in rural areas, foul blots upon fair scenes? It is true protests are raised but the faults continue, while one can imagine that in earlier days, say about 1860, the fervour of the reformers would have swept them away. Let us strive to preserve a balance and, in pursuit of new triumphs, not permit that insidious enemy, dirt, to regain positions from which he has been ousted. Even when dirt does not spell disease it leads to a lowering of tone, to a lack of self-respect, to a slackening of fibre. The trouble is partly due to the fact that much of the sanitation which formerly very closely concerned the medical officer of health has been relegated to other control. In the earlier days he had to fight like the devil, or shall we say like a good angel, to secure pure and sufficient water supplies, to get sewerage systems established, to ensure the healthiness of dwellings. Nowadays, for order has long since succeeded chaos, water supplies, sewerage and sewage works, house drainage and so forth are in the hands of competent engineers. Minor engineering and house sanitation are looked after by well-trained and certificated sanitary inspectors. Good and well, but from what I hear and what I see, I believe it would be an advantage if our medical officers of health had a little more time to keep in personal touch with these matters. This, I believe, is even more true in the case of the removal of nuisances and of refuse, one of the chief environmental duties in the olden days and still in tropical countries a most essential part of the health officer's routine.

As of yore the other environmental deeds comprise action relating to housing and town-planning, smoke prevention, the inspection of food, the control of infectious diseases, and inquiries into offensive trades. I cannot list them all but, with the exception of the control of infectious diseases, they have slipped a little into the background, for a multitude of activities relating to the hygiene of the individual now falls to the lot of the medical officer of health and certain of his assistants. In the matter of practical application these new duties are a product of this century and comprise maternity and child welfare work, the special and intensive control of tuberculosis, and the venereal diseases from the standpoint of the infected individual, the care of the health of the school child, the care of the blind, and occasional duties arising out of the National Health Insurance Act.

Formerly the great idea was to stamp out disease, especially communicable disease. That great idea persists, but along with it there is now the conception of rearing a sound and healthy race from the start, of extending the campaign to diseases called non-communicable, like rheumatism, rickets, and cancer, and even to minor maladies such as dental caries, oral sepsis, discharging ears, habitual constipation, the common but crippling cold, and the dyspepsias which cause so much chronic ill-health and lead to so much inefficiency. There is a move also towards investigating and dealing with worm infestations, which in the past have been somewhat neglected. Lastly, public education in hygiene has become a feature of the new campaign.

Innumerable Helpers.

Enough has been said to indicate that hygiene in this country must now be spelt with a very
evident that the health organisation is
it could scarcely fail to be, considering its origin, the way it developed, the fact that, over a long period of years, there have been shifts and adaptations and modifications, the manner in which new legislation has been grafted upon old, the necessity for conforming to altered conditions of life. Some of the helpers have been mentioned, but there are many others. The school teacher inculcating simple rules of health helps the cause, so does the wise parent, so does the child who puts precepts into practice. The schools of medicine help and will help more when they adopt as the chief object of their training the permeation of the medical curriculum with the preventive idea. Specialist medical officers help, like those in charge of tuberculosis and venereal disease clinics. In this category comes also the school medical officer and, despite all that is urged against him and his doings, the public vaccinator. The medical practitioner helps and his help will increase in value when he coöperates to a greater extent than at present with the officers of the Public Health Service and if and when the

idea of periodical health examinations takes root. The medical press helps and it is gratifying to note how much attention it now pays to the preventive side of medicine. Veterinarians help by dealing with tuberculous milk cows and stamping out diseases of animals transmissible to man. Employers of labour help when they make provision for the welfare of their staffs and employees. The tradesman helps when by his cleanly methods he handles human food in a way to command respect and confidence. I always take my hat off to the maiden in the sweetstuff shop who uses a scoop instead of her hand, be the latter never so dainty.

Those engaged in research help as, for instance, the great army of workers under the aegis of the Medical Research Council and those engaged in many scientific institutions upon problems affecting every branch of hygiene. There are many voluntary agencies, like the League of Red Cross Societies, which help, some more wisely than others, but all in some degree so that we recall an old proverb of Portugal which says: "One grain fills not a sack but helps his fellow." The lay press helps often very greatly; occasionally, perhaps, not to the best advantage, but with opportunities vouchsafed to few of those who aid the cause. Its influence in the past has been widespread and in the future will become more effective when those best fitted to advise the public can make use of its columns for propaganda purposes. The Church helps in various ways and might help more if it recognised to a greater extent that sick bodies are specially apt to be tenanted by sick souls and that there is something to be said for giving bodily and mental hygiene a first innings in any attempt to elevate the masses and improve moral tone. The Law helps, though it is better not to invoke its aid and to try what persuasion and education can do in the first instance.

But the lesson to-day is that everyone can help. There is no mystery about the business. Once a few essential facts are mastered simple rules of health can be adopted and practised by any person of average intelligence. A vast deal of public health practice is common sense applied to everyday affairs. Long ago it was different. A pall of ignorance shrouded the medical faculty and the laity alike. Visitations of disease were supposed to be the outpoured vials of wrath of an outraged deity. Superstition was rampant. Fatalism held sway. The people perished for lack of knowledge. Now all is changed and, though we are still ignorant in certain directions, for example, the causes of influenza, measles, and the so-called "sleepy sickness" still elude us, we have a firm grasp of principles and in large measure are masters of our fate. Who can doubt it? Consider what has happened.

The death-rate of the whole country has fallen to a figure which 50 years ago would have been regarded by many as beyond the dreams of the most optimistic. The infantile mortality has been halved in the course of a generation, the tuberculosis death-rate has steadily declined; some diseases have become extinct, others nearly so. The expectation of life, that is, the number of years a person may expect to live from the time of birth, has greatly increased—i.e., from about 45 in 1900 to 55 to-day. In the U.S.A. it is 58, in New Zealand 62. In British India, a land where hygiene has as yet made little progress, it is only 23. What we now have to fight is not so much death as damage. Life has not only become safer but infinitely more confortable, though there is still great need for improvement.

Monetary Value of Human Life.

The facts are convincing but these kinds of facts do not always appeal to the multitude and, in any case, there are many people, who, quite rightly, always consider the cost, their motto being, "Is the game worth the candle?" and their candle meaning hard cash. Not only so, but perhaps because there was some truth in Napoleon's sneer about a nation of shopkeepers not a few folk in Great Britain and, I take it, the Isle of Man, want return for their outlay, if not actually in what used to be called "jingling Geordies," at least in terms of guineas or of pounds, shillings, and pence. Both classes may rest satisfied for it is well worth while spending money on health, which is in a high degree a purchasable product, and, moreover, hygiene pays. It is a good and sound investment both for the individual and for the nation. If any sceptics remain, they will naturally say, "Submit your proofs and in plain language which can be understood, not camouflaged by scientific verbiage nor rendered unintelligible by the use of what the Scotch call 'lang-nebbit' words." Well, here they are!—a few of them—there is not time for many though they could easily be multiplied.

First, let us consider the monetary value of human life. What is that enigma, a human being, worth in coin of the realm? Well, his or her value varies according to age. The latest calculations come from America and are, of course, not applicable to this country, especially as they are based on earning capacity. However, it is interesting to consider them. Dublin and Lotka have recently shown that in 1924 the potential value of a male child at birth was no less than £1866 and, what is more, they have demonstrated that since 1901 its value has increased by £356, or nearly 20 per cent., owing to improved conditions.

Woods and Metzger have shown that in 1927 the average per capita value of the population of the United States was £3113. There have been more or less vague guesses on the subject this side of the Atlantic and one feels that Dr. Nankivell, the medical officer of health of Plymouth, was distinctly cautious when he said: "It is not an exaggeration to suppose that a life is worth on an average at least £100 to the community." Working on this modest basis and comparing the Plymouth of to-day with that of 70 years ago, he concludes that the improved health of the city represents a large annual financial saving which for 1926 he estimates at £100,000. "Nothing," he says, "costs the individual ratepayer more than sickness and mortality."

There we have a calculation concerned with all kinds of preventable disease. Let us look at another limited to a single malady but a malady which takes heavy toll and which is one of the "Four Scourges" to which Dr. Fremantle devotes a chapter in his interesting book, "The Health of the Nation." The malady is syphilis, that "hidden hand in pathology," as it has been called, and Colonel Harrison, writing about it in England and Wales, points out that "in 1920 there were reported to the clinics about 42,000 cases. Of these probably 6000 would have died of some sequel of syphilis had it not been for the treatment afforded by the free clinics." He assumes that the value of a man's life is £60, which he admits is a very low figure considering that the deaths would have occurred in persons at the most productive period of life. As a matter of fact, £500 would have been nearer the mark, and, as we have seen, in the United States an infinitely larger figure would be quoted. However, if we put it at £60 the loss would have been £360,000 by 1927. This represents only the saving of life. The average patient prior to death is ill for about three years. Hence the system of free treatment, a great ally of hygiene, by which many thousands of people are prevented from becoming burdens on the community at a time of life when they should be national assets, must be of immense value to the nation.

Take another disease—small-pox—which in a mild form we now permit to run riot in certain parts of England. Dr. D. Rocyn-Jones, the county medical officer of Monmouthshire, estimated that the recent small-pox outbreak there had cost the rate-payers £10,000 in capital expenditure and equipment, while the maintenance of 200 beds for six months means another £13,000. That is a pretty state of things brought about by the neglect of a measure the value of which in preventing small-pox has been abundantly proved and proved up to the hilt.

Health and Industry.

Sickness in relation to its cost in industry formed the title of an interesting paper by G. F. McArthur, the chief lady welfare superintendent of the London Midland and Scottish Railway Company. She quotes statistics issued by the Ministry of Health to show that, in 1926, there were 15,000,000 cases of individual sickness drawing benefits under the National Health Insurance Act, and that 27,000,000 weeks of working time were lost owing to illness, much of it, remember, if not most of it, preventable. The loss of wages to the workers is estimated roughly at a minimum of £30,000,000 and this means a corresponding loss to the nation in spending power. There remains the loss to production faintly reflected, as she puts it, in the 27,000,000 weeks of lost working time. Approximate though they admittedly are, these figures are probably under than above the mark and they should give one furiously to think. It must be clear that money spent in diminishing this drain is money well spent, and, as a matter of fact, a comparatively small expenditure will bring about a great reward and in two directions. As McArthur well says: "If every industry would examine its sickness costs with the same thoroughness as it examines its manufacturing costs, and with the same motive of reduction, the result would not only be to bring down the premium of the health insurance societies but to bring 'peace in industry' many milestones nearer its longed-for fulfilment." Prof. E. L. Collis, quoted by Dr. Deardon, is even more emphatic on the "savings" question. He considers that medical science properly applied to British industry would result in an annual saving in labour turnover of from £60,000,000 to £70,000,000, in lost time of £50,000,000 to £60,000,000, in industrial convalescence of many millions more, and that to assess the total saving at £140,000,000 a year would be quite reasonable and well within the range of possibilities. Lastly, for figures are apt to become wearisome, let me refer to an act of great significance. Insurance companies know the value of money and are careful about their investments. The American has never been accused of lack of appreciation of the dollar. Yet we find an American company, the Metropolitan Life Insurance, generously supporting public health work in Canada and the United States. Why? Because it is good business.

There is another aspect to this financial question which strengthens the argument that hygienic measures pay. In the absence of adequate preventive measures employers of labour may have to compensate their workpeople. Not very long ago, the widow of a coal-miner in Scotland obtained compensation because it was shown that her husband had died of a disease called infectious jaundice and that he had become infected in the pit from a rat or rats harbouring the parasite of that disease.

Sound Investments.

With all these facts and figures before us what are the investments which can safely be recommended to the inhabitants of this island? From a study of statistics and from information kindly supplied, it is clear that antituberculosis gilt-edged stock, if it can be secured, would yield good returns. Well, it can be got if, at the same time, we take some ordinary temperance, I do not say teetotal, shares and secure also some housing debentures. I call these debentures because money put into good houses and devoted to lessening overcrowding may well result in a repayment of principal in addition to interest. Segregation cumulative preference shares may be commended. In other words, put money into an hospital where cases of communicable disease can be received and the danger of spread of infection thereby lessened. Little or no result may be seen in one year but the time will come when this investment will prove a boon and a blessing. Milk bonds are indicated, for there is much need for the consumption of more milk and such milk should be pure and cheap. Douglas has already put money into what we may call ordinary water shares with the ordinary result, which at one time would have been looked upon as extraordinary, that typhoid fever has been abolished in the town. It still, however, lingers in the other districts and so antityphoid stock is indicated for purchase. It is, as has been hinted, of different kinds. Finally, funds may well be devoted to obtaining education trustee securities, another gilt-edged stock. Making ourselves trustees for public health propaganda we can put money into this type of investment without being liable for depreciation. In any case, there should be no depreciation, nor should any of these ventures fail. The Isle of Man is favoured in many ways. It is comparatively isolated during part of the year, and isolation in health matters has its advantages. Its climate has much to commend it. It enjoys a fair measure of prosperity and yet is free from the graver industrial problems. It is interested economically in keeping healthy, for it derives much of its revenue from its visitors, and typhoid and tourists are incompatible. Its death-rate, 14·6 per 1000 in 1926, is a fairly respectable figure and is less than its birth-rate. Its infantile mortality-rate is not very high and is improving. Altogether it would appear as if the Isle of Man, starting, it is hoped, on a new race for health, has an excellent handicap. There really seems no reason why it should not achieve a record. It would be a proud boast in years to come if this little island could wrest the laurel wreath from another island, from New Zealand, which has already achieved several records and is all out to make others. It is worth trying, for everyone benefits in the process except perhaps undertakers, sextons, and the proprietors of cemeteries and crematoria, and, after all, these good folk can never be quite ruined, for all must, in the long run, die. The great thing, however, is to die as we are meant to die, peacefully at a good old age, and to live as we are meant to live, healthily with sound minds in sound bodies.

ASSESSMENT OF RATES ON HOSPITAL BUILDINGS.

A MEETING was held at Brighton on June 26th to consider the position of charitable bodies under the new assessment of rates in the borough brought about by the Rating and Valuation Act, 1925. Mr. A. F. Graves, who has for many years been connected with a number of Brighton institutions, expressed the opinion that the assessments which the corporation valuer had arrived at were far too high. The institutions had, since 1875, been assessed at nominal figures, but the valuer had now assessed them at what he considered to be their true value, and no one, except Parliament, could alter those arrangements. Unfortunately, Mr. Graves said, the corporation had brought the Act into operation earlier than any other corporation in England, and that made it extraordinarily difficult to ascertain how charities were being treated elsewhere.

Mr. Graves had attempted to ascertain the position of institutions in other towns of about the same size as Brighton. At Burnley the hospitals were not assessed at their full value; in Sheffield special consideration was given them, the assessment working out at £1 per bed. In Birmingham and Portsmouth the cases were dealt with on their merits; and in Leeds the institutions were not assessed at their full rack rental, some concession being made. Mr. Graves contrasted the case of the Sheffield hospitals, rated at £1 per bed, with the position of the Royal Alexandra Hospital for Sick Children at Brighton, the new assessment of which worked out at £14 per bed. Even London hospitals, occupying sites the rental value of which must be enormous, were only assessed at £4 per bed. Mr. Graves instanced three examples of the effect of the new assessment at Brighton. The Royal Sussex County, which formerly paid £100 a year, was faced with a demand for £1600 a year in rates; the Children's Hospital demand had jumped from £16 to £500; and the Eye Hospital had gone up to £100 from its former figure of £17. As to the Children's Hospital, the amount to be paid in rates would practically absorb the whole of its income from subscriptions. It was impossible for the hospitals to raise the extra money to meet the extra demand. If the position was not cleared, hospitals and institutions would not be able to build an addition to their buildings, because they would be rated on them at the higher rate.

A resolution was carried requesting the borough Members of Parliament to take steps to secure the passing of a short Act of Parliament, or such other measures, for relieving hospitals and other charities of the liability for paying rates under the assessments being placed on charitable institutions under the Rating and Valuation Act, 1925, and that the Town Council be requested to receive a deputation from that meeting to discuss the effect of the new assessments upon local charities.

A BRUTAL SCHOOLMASTER.[1]

AN English translation by Mr. Cyrus Brooks, of the well-known German novel, "Die Ursache," explains fully the popularity of the original and justifies the reputation of the author. The story is simple, terrible, and, which is not the case as a rule with terrible stories, perfectly coherent. A young poet and journalist, who has suffered greatly under a brutal schoolmaster, on visiting his old school, finds the pedagogue maltreating a pupil with similar callousness. Accordingly he kills him, on impulse, and attempts, in defending himself on the charge of murder, to explain the excellent social motives which had led to the crime. Unfortunately he had taken a bank-note belonging to the victim in order to make good his escape, and so comprehensible a reason for the crime neutralises a defence which otherwise might have been regarded as a plea of lunacy. One juryman only inclines towards leniency, recognising something of the murderer's mental state. In describing the last hours and execution of the wretched convict, no details are omitted that might add to the horror of the situation. As a study in psychiatry (perhaps) and as an example of the literature of the terrible (certainly) the book is worth reading. The point of view of the criminal is, presumably, that his crime was justified, or had followed necessarily upon the resuscitated experiences of childhood; the jury only saw in it an ordinary case of theft with murderous violence. The verdict of an ordinary jury was inevitable, even though the mentality of the poet was misunderstood; a jury of psychologists might have been willing to substitute life-long confinement for the death sentence.

HOSPITALS FOR MIDDLE CLASSES: AN APPEAL.

AT the recent conference of the British Hospitals Association, Sir Thomas Horder referred to the need for some alternative to the private nursing home for patients of limited means. The administrator of St. Andrew's Hospital, Dollis Hill, Mr. W. E. Carton de Wiart, points out to us that a beginning in this direction was made as far back as 1913, when the institution over which he watches was opened for the reception of patients, who, while not suitable subjects for free treatment in charitable institutions, were yet unable to meet the charges necessary to secure adequate medical or surgical treatment in private nursing homes. This institution, which depends for its maintenance upon voluntary contributions and patients' payments, stands in its own grounds of 17 acres and is equipped with all modern requirements, while patients are admitted only on the recommendation of their medical adviser; there are no restrictions either as to nationality or creed. As the hospital is now well known, its accommodation of 52 beds is, of course, taxed beyond its limits, and there is urgent need for increasing the number of beds, and for the provision of a children's ward. The domestic provision for the staff, already inadequate, would become more so as a result of the enlargements. The improvements urgently needed are estimated to cost £30,000, and towards this sum £6600 are already available, and builders' plans have been prepared. If the necessary financial help were forthcoming, extension operations could proceed at once. Full particulars will be supplied on application to the Administrator, who makes out a good case for prompt assistance.

Observations
ON
DIVERTICULA OF THE COLON:
A PATHOLOGICAL AND CLINICAL STUDY.

By ROBERT MAILER, M.D.Edin., M.S.Minn.,
F.R.C.S.Edin.,
ASSISTANT SURGEON, VICTORIA INFIRMARY, GLASGOW; LATE FELLOW IN SURGERY, MAYO FOUNDATION, ROCHESTER, MINNESOTA.

In 1858, at a meeting of the Pathological Society of London, Sydney Jones reported the case of a man who had suffered from a fistulous communication between the bladder and the bowel, secondary to an inflamed and ulcerated diverticulum of the sigmoid flexure. In spite of this striking demonstration, nearly 70 years ago, of the existence of diverticula of the large bowel as distinct entities, and also of their rôle in the production of grave pathological processes, it was not until 1898 that Graser, by emphasising their importance in the production of stenosing types of inflammation simulating carcinoma, caused attention to be seriously focused on them for the first time. Then the contributions of Mayo, Wilson and Giffin, Beer and Brewer in America, and of Moynihan and Telling in England, established diverticulitis as a well-defined clinical entity with definite sequelæ. In spite of the extensive literature which has since grown up around the subject, diverticulitis cannot be said to be a common disease. At the Mayo Clinic, however, such a wealth of clinical and pathological material bearing on this subject has been available that a study of the disease from all aspects has been rendered possible. Especially has one been able to collect data with reference to the frequency of occurrence of diverticula of the lower bowel, the frequency and character of the pathological changes which may be superadded, as well as to those measures which have been found most successful in the treatment of the latter. The material has been gathered from the post-mortem room, and from the operating room were obtained resected specimens from cases of surgical diverticulitis. For clinical data, the records of cases occurring at the Mayo Clinic during the last 15 years have been consulted.

Incidence and Distribution.

The most recent radiological records of the incidence of diverticula are those by Spriggs and Larimore. In a series of 1000 radiological examinations of the colon Spriggs found diverticula in 10 per cent. Larimore found diverticula in 1·24 per cent. of 4406 cases. At the Mayo Clinic, in 1925, diverticula were found in 5 per cent. of cases in a series of 4484 radiological examinations of the colon. From April 1st, 1923, to April 1st, 1924, in 498 necropsies at the Clinic (excluding partial necropsies and necropsies on still-born children), diverticula were found in 34 cases (about 7 per cent.). All but two of the patients in this series were over 45 years of age. Making the necessary corrections, one could say that roughly 13 per cent., or one person in eight over the age of 45, showed diverticular formation in the large bowel. It was found almost twice as often in men as in women, although there was no marked preponderance of males over females in the total series studied.

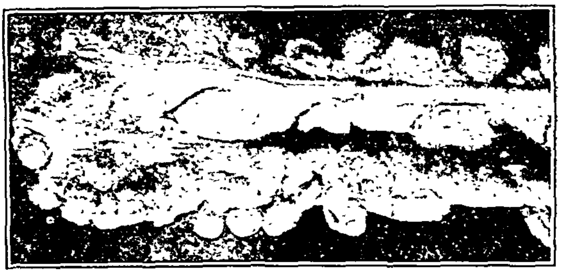
In 53 specimens examined, diverticula were confined to the sigmoid flexure alone in 22 cases (40 per cent.). They were scattered throughout the entire colon in 16 cases (30 per cent.). Rarely the cæcum, ascending colon, splenic flexure, and upper rectum were each involved, alone or with the sigmoid. The point to be emphasised is that the sigmoid is involved in between 70 and 80 per cent. of the total number of cases showing diverticular formation; these findings correspond closely with those determined by X ray examination. Moynihan stresses the appendix as a very common site; this was not borne out in the post mortem series examined.

Macroscopic Appearance.

Diverticula in the large bowel vary from almost microscopic dimensions to about 2 cm. in diameter. They have been seen as large as 4 cm. in diameter, but this is exceptional, and there appears to be definite limitation to their capacity for growth and development.

In situ they are almost completely concealed from view because of their tendency to occur in that part of the intestine that is heavily laden with fat. The increase of the subserous fat and the coalescence of the appendices epiploicæ may cause a distinctive tuberous appearance of the bowel. When the fat is stripped, the diverticula are seen typically as bluish-black flask-shaped or pyriform outpouchings, set roughly in two parallel rows. This colour is distinctive of the so-called false diverticulum, in which mucosa and submucosa are herniated through the muscular coat. At the base or neck, the muscularis passes up for a short distance on the wall of the diverticulum, forming a narrow whitish strip or collar which is easily distinguished from the bluish fundus or cupola beyond. Only about 75 per cent. of the cases examined, however, showed increase in the subserous fat and in the size of the appendices epiploicæ. In the remainder, where there was no such increase, the patients were either old or had died from malignant disease in which cachexia was prominent. In one or two instances the fatty increase appeared to be strictly localised to the site of the diverticula. This may be explained partly by the tendency of diverticula to extend into and expand the appendices epiploicæ.

FIG. 1.



Multiple diverticula of the sigmoid flexure. The fat of the epiploic appendages has been removed to demonstrate the sac more clearly. Relationship to the longitudinal muscle bands and disposition roughly in two rows may be noted.

The bluish-black appearance of false diverticula is dependent on the presence of fæcal matter within the lumen. Fæcoliths, however, are not invariably found, even in sigmoid diverticula, although spasticity in this area, coupled with the inspissated nature of the intestinal contents, certainly makes them common. Small diverticula with wide mouths, occurring in the non-spastic bowel, often contain no fæcal matter at the time of examination, and are pale and collapsed. Viewed from the mucosal aspect of the bowel, the appearances depend on the presence of spasticity or rugosity of the mucosa. In about 60 per cent. of the series examined, the mucosa of the sigmoid was thrown into rugæ, running slightly obliquely, and the openings of the diverticula were in the depths of the furrows so formed. In the sigmoid the orifices usually appeared as small slits, elongated in the direction of the rugæ. Where diverticula appeared in a non-spastic gut, the orifices tended to be wider, and the mucosa of the diverticula tended to prolapse slightly into the main lumen of the bowel, so that the orifice appeared as if set on a small papilla.

Even when diverticula are multiple throughout the colon, they are almost invariably scarce in the cæcum and ascending colon. Moreover, they are smaller than diverticula of the sigmoid, for they are not subjected to the stretching dependent on the accumulation of fæcal matter within them. Spasticity in this portion is usually absent, the orifices of the diverticula are wide and generally somewhat raised from the plane of the mucosa of the bowel, producing the papillar appearance. These diverticula are usually empty, and can be readily invaginated into the interior of the bowel. The transverse colon, on the other hand, is often spastic, and the multiple small segmentations into which this portion is thrown by the contraction of the longitudinal tæniæ may give, prima facie, a close mimicry of diverticular formation.

Although diverticula may be numerous in the lower sigmoid, they are rare in the upper rectum, probably owing to the greater thickness of its wall. The rectum was affected in two cases only in the series studied.

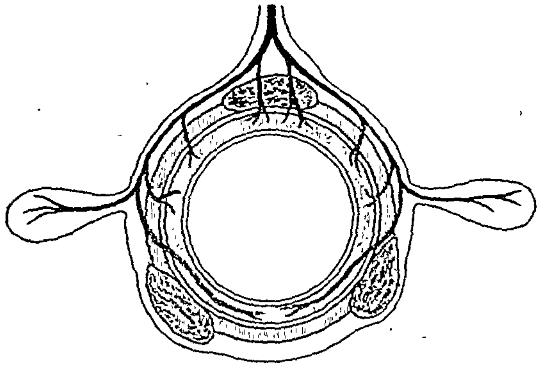
Their Site in Relation to Circumference of the Bowel.

The exact situation of diverticula in relation to the circumference of the bowel is remarkably constant. They appear between the mesocolic and the antimesenteric longitudinal muscle bands, rather closer to the latter than to the former. The diverticula are definitely related to the blood-vessels entering from the mesentery.

It will be seen from Fig. 2 how easy it is for a diverticulum, once it has extended beyond the plane of the muscular coat, to pass into an appendix epiploica. While this is common, it is not invariable. I have never seen diverticula of the large bowel entering between the two leaves of the mesentery as diverticula of the small intestine are so apt to do, and in only one instance have I seen them appearing on the antimesenteric aspect of the bowel between the two antimesenteric muscle bands. When numerous in the sigmoid, however, they may not confine themselves strictly to the vessel points, but, as a result of the generalised weakening of the musculature, they may crop out promiscuously all over the area between the mesocolic and the antimesenteric longitudinal muscle bands. I have seen one instance in which the diverticula were splitting the fibres of the longitudinal muscle band.

The segmental contractions of the bowel force fæcal matter into the diverticula and the narrow orifices, and the lack of muscular coat in the expanded portions prevents its expulsion. The fæcal matter becomes moulded to the shape of the diverticular cavity and forms a concretion which usually resembles closely, both in shape and consistency, those in the appendix. They are easily removable, although occasionally I have seen them so closely incorporated with, and adherent to, the mucosal lining of the sac that the lining was completely stripped off by the attempt to remove the concretion. Even in the sigmoid, however, the contents of the diverticula are often quite soft, and in the remaining portion of the large intestine, particularly the ascending and transverse colon, the diverticula are often empty, or are filled with soft fæcal matter. This, of course, is due largely to the well-established physiological fact that, generally speaking, the contents of the right half of the colon are fluid and of the left half solid.

FIG. 2.



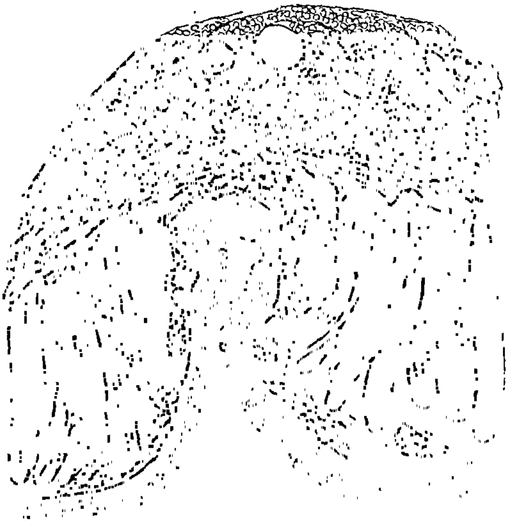
The point near the antimesenteric muscle bands, where the muscular coat is pierced by the blood-vessel entering from the mesentery, is an area of lessened resistance, and constitutes the seat of election for diverticula (after Drummond).

Development and Microscopic Anatomy of Diverticula.

Diverticula first appear as little pits in the mucosa. Mucosa and submucosa then extend up through the circular muscle coat, and in the earliest stages may look like exaggerated spasticity of the bowel.

Arriving at the longitudinal muscle coat, the growing diverticulum either breaks through this or carries it in front of it. In Fig. 3, both circular and longitudinal coats have given way, and the outpouching is ready to extend beyond the plane of the bowel as a so-called "false" diverticulum. In other cases the longitudinal coat, although thin, appears to remain intact for a considerable time, but ultimately undergoes pressure atrophy from the continued growth of the diverticulum. In Fig. 4, for instance, muscular fibres can be traced along the wall of the diverticulum for at least half the distance towards the fundus. Beyond this, Van Gieson's stain demonstrated considerably fragmented muscle-fibres around the fundus of the saccule, gradually being replaced by fibrous connective tissue. The ultimate outcome, in most cases, is a diverticulum of the "false" type, lacking muscular coat.

FIG. 3.



Camera lucida drawing of a diverticulum. The sac is breaking through the longitudinal muscle coat.

Fig. 4 is typical of the appearance of the average false diverticulum of the sigmoid. It shows the rather redundant mucosa of the main lumen of the bowel, the narrow neck of the diverticulum where it passes through the muscular coat, and where, in the absence of a fæcolith extending to the orifice, the spasticity keeps the opposing walls in contact. Beyond is the pyriform expansion into the appendix epiploica. The mucous lining of the diverticulum is normal.

I believe the final tendency in all diverticula of the large bowel is towards the production of the false type of sac. On the other hand, in a certain proportion of diverticula a muscular coat is retained, and these can be classified as true diverticula. At the same time, it is probable that they are simply stages in the development towards the false type. Again, if chronic inflammatory changes develop around diverticula, their further growth tends to be arrested.

ÆTIOLOGY.

The first aspect of the problem to be considered is whether the diverticula are congenital or acquired, or whether there are two distinct types. The fact that several cases have been described at early ages favours a congenital basis, and there is also the association, in a proportion of cases, with diverticula elsewhere in the body. In the 53 cases examined post mortem, diverticula of the colon were found associated with diverticula of the duodenum in four cases, with diverticula of the jejunum in two, and with diverticula of the bladder in two. In other words, the coexistence is not common enough to favour a congenital origin. That diverticula of the colon are sometimes congenital must, *I think*, be admitted, but they are rare. The cases reported by Hartwell and by Fütterer and Mitteldorph are undoubtedly congenital.

Acquired Diverticula.—As a rule, the occurrence of diverticula in middle and later life is overwhelming vidence that they are acquired. The age-incidence n 100 cases of diverticulitis verified by operation is shown in Table I. Eighty-five per cent. of the patients in this series were between the ages of 40 and 70, so that apparently diverticula begin to affect persons in middle life, and are especially common in advanced middle age and old age.

TABLE I.—*Age-incidence in 100 Cases of Diverticulitis.*

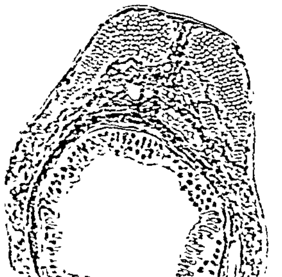
Age.	M.	F.	Age.	M.	F
20 to 30	0	1	50 to 60	25	11
30 to 40	6	4	60 to 70	19	5
40 to 50	17	8	70 to 80	3	1

TABLE II.—*Average Weight of Patients in Clinical Series.*

—	Cases.	Av. weight in lb. previous to onset of symptoms.	Av. weight in lb. at time of exam.
Males	55	179	166
Females	20	157	149

The earlier observers, including Graser and Hansemann, stressed the repeated increases in pressure from constipation and gaseous distension as being important factors in ætiology, but there are many reasons for believing that if the wall of the bowel is of normal elasticity there is no apparent distension clinically which will produce diverticula. Again, though Graser, Hansemann, Hanau, and Klebs concentrated on the vessel points in the bowel wall as constituting the key to the ætiology of diverticula, these vessel points are probably to be regarded more correctly as determining the site of the diverticula than as important ætiological factors in their formation. Most observers have noted the tendency for diverticula to occur in rather obese persons, but the obesity in these cases is most probably the concomitant of middle age and its attendant restricted physical activity, with resultant lowered plane of metabolism and less perfect oxygenation of the tissues. With few exceptions diverticula occur after the age of 40, when the patient is entering on the degenerative period of life. It seems logical enough to assume that the loss of tone and elasticity of muscle which accompanies advancing years is not confined to striated muscle, but affects the unstriped muscle throughout the body, including that of the intestine. Recently Spriggs and Marxer, from a series of excellent radiological studies, suggest that the diverticula may result from a preceding inflammatory process, but in my own pathological studies I was unable to demonstrate this.

FIG. 4.



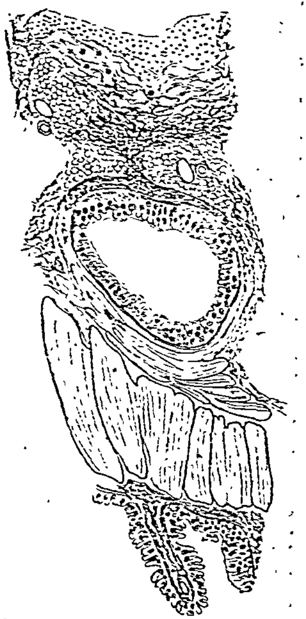
Camera lucida drawing of a diverticulum passing into the epiploic appendage. Muscle - fibres were demonstrated around the fundus of the diverticulum. A mild degree of subserous fibrosis may be noted.

SECONDARY CHANGES.

The secondary pathological processes superimposed on diverticula may be divided into mechanical and inflammatory.

Mechanical Processes.—Fæcal concretions may produce mechanical irritation of the mucosa of the diverticulum, bringing about a condition favourable to the multiplication of micro-organisms and to their passage beyond the lumen of the diverticulum. Since concretions of considerable hardness are found only in the sigmoid flexure, it follows that for practical purposes inflammatory conditions superimposed on diverticula are confined to this region. The right half of the colon, where the intestinal contents are fluid, is practically immune. However, it is remarkable to what extent the mucosal lining of a diverticulum may be thinned out through pressure atrophy from a concretion and yet inflammatory changes be absent. Fæcal concretions often project slightly into the main lumen of the bowel and the tip may be exposed to pressure from the main bulk of the fæcal mass. Cases of sudden pistol-shot perforation occurring during strain have been described by Murray. In the series of cases at the Mayo Clinic there was no record of such an accident. The presence of foreign bodies other than fæcal concretions has been described by Bland-Sutton. These have been accused of setting up inflammation.

FIG. 5.



Diverticulum in cross section. A collection of lymphocytes, and, incidentally, grades of inflammatory reaction in the subserous coat may be noted.

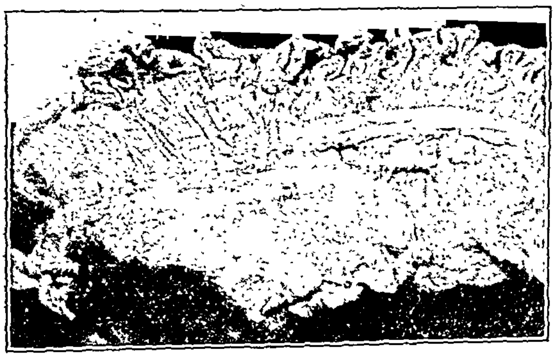
Inflammatory Changes in Diverticula.—Theoretically, one would consider the diverticulum with its irritating and infected fæcal contents to be an ideal nidus for the development of micro-organisms, and for the occurrence of inflammation of varying grades of severity. This does certainly occur, but comparatively seldom. Of 34 cases in which diverticula were found post mortem in one year, only one showed chronic inflammatory subserous changes of any degree of severity, and even in this case the inflammation was latent and asymptomatic. Three or four cases showed microscopically mild chronic inflammatory changes in the subserous fat. In the remainder no inflammatory changes were found. This point is worth emphasising. Radiologically, diverticula are by far the most common lesions in the colon; they are at least three times more common than the next most common lesions—namely, carcinoma and ulcerative colitis. Diverticulitis, on the other hand, is rare, and probably not more than 10 per cent. of the cases ever require surgical intervention for gross inflammatory complications. It is for this reason that the term diverticulosis, referring to the mere presence of uncomplicated diverticula, is preferable; the term diverticulitis should be reserved for the relatively small number of cases that give evidence of superadded inflammation.

Inflammatory changes in and around diverticula may be arbitrarily divided into acute and chronic. Acute infections are often superimposed on chronic inflammatory changes and the latter are much more common.

In the *mild* types, little may be seen by the naked eye to draw attention to secondary inflammatory changes. Often, however, the fat of the appendices epiploicæ is rather coarser and more fibrous than usual. Microscopically, the mucosa of the diverticulum may be almost normal, or slightly atrophied from the pressure of the concretion. Towards the fundus or apex of the diverticulum small collections of lymphocytic cells may be seen in the deeper parts of the mucosa (Fig. 5). These are irregular in distribution and may overlap the muscularis mucosæ so as to give the appearance of gaps in its continuity. These collections of lymphocytic cells resemble lymphoid follicles except that they are irregular in shape and distribution and do not have the appearance of a germinal centre. The solitary follicles may be found lying alongside them and are then quite easily distinguished. These lymphocytes are the response to the extension from the cavity of the diverticulum into the surrounding tissues of an attenuated poison—toxins of bacteria rather than the bacteria themselves. Outside the diverticulum there is some fibrous connective tissue in the immediate neighbourhood of the fundus, indicating the source of the chronic irritation from which it originated. The submucous fibrous coat, which followed the mucosa in its herniation through the muscle, is compressed into a compact and dense layer which usually cannot be well distinguished from the new fibrous connective tissue.

The *severer* grades of chronic inflammation are far more important from the surgical standpoint. In Fig. 6 the long narrow diverticula are seen passing up between the rugæ and extending beyond the muscular coat. In the subserous coat the thick layer of fat has been almost entirely replaced by dense white fibrous connective tissue, forming a homogeneous layer about 3 cm. in thickness, dull pearly-white, and cutting almost with the consistency of an unripe pear, so that it closely resembles carcinoma. Under the microscope, the mucosa, submucosa, and muscle coat show practically no changes, and there may be only very slight evidence of chronic inflammation in the mucosa of the diverticulum, manifested by a few foci of lymphocytes towards the fundus, slight mucosal atrophy, and diminution in the number of the gland crypts. The changes in the neighbouring subserous coat are most striking. It is for this reason that Wilson some years ago suggested the term "peridiverticulitis" as being more appropriate. All grades of transition from the original subserous fat to complete replacement by dense fibrous connective tissue are met with. The fibrous tissue is denser and less cellular in the immediate vicinity of the diverticula, while beyond, where the fat replacement is not complete, the connective tissue is younger and more vascular, and cells of inflammatory origin may be present. Small collections of lymphocytic cells are found in the region of the blood-vessels, and are sometimes seen extending in long lines along the lymph spaces between the fat cells. Fibroblasts appear, and young cellular and vascular tissue is formed. Towards the serous coat the process is less advanced, and fibrocellular strands can be seen extending between the fat cells (Fig. 7). Besides lymphocytes, there are lamellar connective tissue cells and plasma cells. Plasma cells, however, are seen only in the subacute or acute types of inflammation.

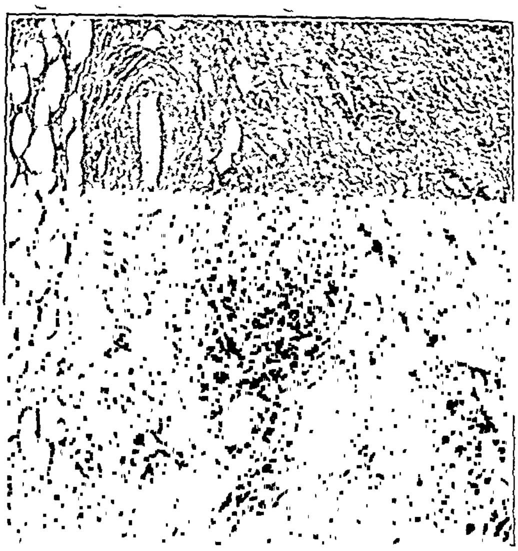
FIG. 6.



Portion of sigmoid removed at operation showing fairly typical diverticulitis and peridiverticulitis.

The final tendency is towards the formation of dense and more avascular connective tissue, replacing the normal structure of the subserous coat of the bowel. This renders the intestinal wall rigid, so that it loses its contractile and propulsive character and favours stasis. Again, the contraction of the fibrous tissue increases the already existing rugosity of the mucosa and consequently reduces the lumen. The last factor which may aid in the production of obstruction is angulation of the bowel, which is the result of adhesions and chronic inflammatory changes in the mesentery of the sigmoid. Peridiverticulitis of any degree is rarely present without some coexisting reaction of the peritoneal coat, and often the reaction is more acute in the peritoneum than throughout the rest of the bowel wall. The mobility of the sigmoid, together with this adhesive peritonitis, results in adhesions to adjacent viscera, and also of one loop of sigmoid to another; the latter is still further favoured by chronic inflammatory changes in the sigmoid mesentery, which shorten it and approximate adjacent loops.

FIG. 7.



A portion of the subserous coat of the bowel, the seat of peridiverticulitis. A collection of lymphocytic cells, and early replacement of the fat by fibrous connective tissue, may be noted. (×150.)

The occurrence of acute inflammation in and around diverticula is dependent on the presence of particularly virulent micro-organisms rather than on any great weakening of the defensive barrier formed by the wall of the diverticulum. The most common organism found is a diplo-streptococcus, and this is often associated with Gram-positive bacilli resembling the anaerobic Welch bacillus. These acute inflammatory changes can be divided into two groups: those in which there is gross rupture of the wall of the diverticulum, and those in which the inflammatory changes within the diverticulum are milder, and the wall of the diverticulum apparently becomes permeable to micro-organisms without any demonstrable solution in its continuity. In the latter group it is often difficult to identify the diverticulum or, more rarely, diverticula responsible for the acute inflammatory changes. In the first group it is much easier, for there is usually an intense inflammatory zone, visible macroscopically, immediately surrounding the diverticulum. In the cases in which the diverticula are apparently intact, the organisms pass to the surface and the peritoneum shows the greatest degree of reaction, while the other coats may show relatively little change. It is this type of case which presented so much difficulty in the days before the significance of diverticula was recognised, and it was thought that the source of the peritonitis was extrinsic to the bowel. This is the "pericolitis sinistra" of Rolleston.

Acute inflammatory complications in and around diverticula can occur either as the first manifestation of infection in the diverticula, or in association with chronic peridiverticulitis of long standing; these may present considerable differences as regards prognosis and sequelæ. Diverticula with a thin fatty subserous covering, in which fibrous changes are slight or absent, readily permit of acute involvement of the peritoneum. Inasmuch as no adhesions have formed, the resultant peritonitis may be widespread, though it rarely becomes generalised. On the other hand, if the diverticula are embedded in a thick layer of fat, and especially if there has been considerable subserous fibrosis, acute infection will travel to the surface just the same, but the sigmoid will have formed adhesions to the side wall of the pelvis or to adjacent viscera and a localised abscess is the most serious complication likely to result.

In the central area of the lumen of the diverticulum (Fig. 8) a portion of the inflammatory exudate, consisting of polymorphonuclear leucocytes, may be seen held together by a small quantity of fibrin. The gland crypts show necrosis of portions en masse, and the process is not so much a simple catarrhal desquamation of cells as a more severe type of inflammation in which necrosis is the prominent feature. Several of the crypts are seen to contain inflammatory cellular exudate, and one of the outlying crypts is seen to have perforated. The muscularis mucosæ and the submucous coat around the apex of the diverticulum have disappeared, and the subserous fibrous connective tissue in the immediate zone has been replaced by massive cellular exudation in which polymorphonuclears, lymphocytes, and plasma cells are intermingled. The reaction outside the diverticulum is more marked than in the diverticulum itself, probably because the main blood-vessels are just outside the sac, and the exudative phenomena are more prominent there. Towards the serous coat, the inflammation is subacute, but well-marked acute peritonitis is present. The microscopic picture in these cases of acute diverticulitis varies a little according to the virulence of the reaction, but the foregoing features are fairly typical. To these may be added great distension of the lymph spaces with serum, distension and congestion of blood-vessels, and sometimes small localised abscesses in the subserous coat.

SEQUELÆ.

All grades of severity of peritonitis occur, depending on the virulence of the original infection. Unlike the similar process in the appendix, acute diverticulitis rarely gives rise to generalised peritonitis. Localised pelvic peritonitis or localised abscess is the usual sequel. In 74 cases of peritonitis and abscess, 24 presented evidence of acute peritonitis, invariably localised to the pelvis, and in 15 cases an abscess or abscesses were present (Table III). In 10 cases the peritonitis was classified as subacute at the time of operation, and in 26 cases it was chronic, manifested by adhesions to neighbouring viscera. In five cases the lesion was mainly in the mesentery, one case showing acute mesenteritis. In one instance, multiple small abscesses were found, but in the remainder of the 15 cases the abscess was single. Inasmuch as these abscesses are usually found in a mass of adhesions, they may have existed for a considerable time previous to operation; as a consequence, the pus in the older abscesses is often thick and sterile. They rarely contain more than 30 c.cm. of pus. Occasionally, however, when they have formed under the abdominal wall, they have been incised through the skin and considerable pus evacuated.

Adhesions.—There is a distinct tendency for the sigmoid, which is the seat of diverticulitis and peridiverticulitis, to become adherent to surrounding structures, and this is favoured by the mobility of the sigmoid loop. The adhesions may localise infection, but they also predispose to formation of the fistula and may make radical surgical procedures difficult. Of 100 cases of diverticulitis investigated, adhesions were present in 74. The organs or structures to which the sigmoid was found adherent, together with the relative frequency of these adhesions, is given in Table IV. Adhesions to the bladder are the most common and the most significant. In 14 of the 24 cases, a vesico-sigmoidal fistula had formed. In the 20 cases in which the sigmoid was adherent to the side wall of the pelvis, the most vital structures affected were the left common iliac vessels and the left ureter. In nine cases the left ureter was densely bound down in adhesions, and in one case there was sufficient obstruction to the lower end to produce marked dilatation above. In only one of the 12 cases in which the sigmoid was adherent to the small intestine had actual perforation taken place. In one of the five cases in which the cæcum and appendix were adherent, the tip of the appendix was found lying in an abscess between the sigmoid and the cæcum, but the source of the abscess was diverticulitis and not appendicitis.

Association of Diverticulitis with Carcinoma and Tuberculosis.

Carcinoma of the sigmoid occurs with diverticula in certain cases. In 1917 W. J. Mayo reported it in 13 out of a series of 42 cases. Inasmuch as chronic irritation in other situations has long been recognised as a factor in the production of cancer, it is certainly plausible to regard prolonged diverticulitis as a precancerous condition. Wilson, as early as 1911, drew attention to the apparently close relationship of the two conditions and reported four cases.

I have examined eight cases in which diverticula or diverticulitis coexisted with carcinoma. Without giving the detailed macroscopic and microscopic descriptions on which my opinions are based, I would summarise my findings by saying that the question whether the carcinoma develops propter hoc and not simply post hoc must remain undecided, but my impression is that the malignant process starts in the main lumen of the bowel and not in the diverticula, although the latter may be involved by extension. The gross inflammatory changes in these cases are, I believe, more often dependent on the malignant disease than on the diverticula. It is impossible to determine whether a chronic inflammatory process affecting chiefly the subserous layer can have much effect in determining the genesis of carcinoma in the main lumen of the bowel. In one case the carcinoma involved the recto-sigmoid, while the mass from peridiverticulitis formed a localised tumour several inches higher in the sigmoid, the intervening area of bowel being apparently normal. W. J. Mayo states that, excluding the stomach, most gastro-intestinal cancers are situated at the recto-sigmoid. Diverticulitis, on the other hand, is just as likely to affect the sigmoid higher up. Since approximately one person in every eight over the age of 45 has diverticula of the sigmoid, and since diverticulitis and carcinoma are most common at the same age period, it is reasonable to assume that they will coexist in a certain proportion of cases. I believe that the degenerative changes in the sigmoid consequent on advanced middle age, constitute a common factor responsible both for the occurrence of diverticula and for the higher incidence of carcinoma at this age.

In two cases tuberculosis of the sigmoid was found coexistent with diverticulitis. These are discussed in another article. Hyperplastic tuberculosis of the sigmoid gives a pathological appearance which is almost identical with that of diverticulitis, and when both occur in the same segment of bowel, there is great difficulty in assessing the rôle which each plays in the pathological picture produced.

CLINICAL FEATURES.

In the absence of inflammatory changes, diverticula may not cause symptoms. However, the colon which is the seat of diverticulosis is often spastic and there may be considerable constipation. Even then it may be difficult to determine whether the constipation is due to diverticula or to the habit of the individual. On the other hand, this spasticity may be so marked as to cause symptoms suggestive of organic obstruction, and one is frequently surprised at operation to find but slight interference with the calibre of the bowel when the severity of the clinical symptoms had suggested moderately severe organic stenosis. Again, when inflammatory complications are present, even though there are only one or two diverticula in the sigmoid, one may become acutely inflamed and thus bring the patient to the surgeon. In such cases obstruction may not be a feature, and there may be little previous history to direct one's attention to diverticulosis of the sigmoid as the probable ætiological agent. In most cases there is gradually increasing stenosis of the bowel from chronic diverticulitis and peridiverticulitis, producing more or less constipation. From time to time, however, superadded acute inflammation may cause a flare-up, during which the sigmoid becomes swollen and tender, and partial or complete obstruction may supervene. The patient may seek advice during the first of these attacks, or may pass through several of them with partial or complete relief in the intervening period. Many of the patients come to the physician with complaints which immediately suggest an investigation of the left lower quadrant of the abdomen, but this is not invariable (Table V.).

TABLE V.—*Primary Complaint in Cases of Diverticulitis.*

	Cases.

Urinary symptoms	16
Pain in both lower quadrants	11
Increasing constipation	13
Abdominal pain not localised	8
Epigastric distress	4
Pain in region of umbilicus	3
Pain in rectum	3
Bleeding from the bowel	5
Diarrhœa	4

Classification of Cases.

I found that these 100 cases fell, roughly, into six groups.

Group 1 is made up of cases in which there was a long history, extending over months or years, of gradually increasing intestinal symptoms ultimately amounting to chronic obstruction, or terminating more abruptly in subacute or acute obstruction. It comprised 28 cases, in 11 of which the symptoms terminated in an acute attack, and in one in a subacute attack. In the remaining 16, the symptoms were those of gradually increasing constipation, but without any acute or subacute attack.

In *Group* 2 there was a history of repeated attacks of acute or subacute obstruction with intervening periods of almost complete freedom from symptoms, or at the most only constipation. There were 29 cases in this group; in all but two there was a history of two or more acute or subacute attacks.

Group 3 is a combination of the two preceding groups; there was an early history of months or years of gradually increasing constipation, followed by a period in which there were repeated attacks of acute or subacute obstruction ultimately demanding medical aid. This group comprised 12 cases.

Group 4 comprised 16 cases in which genito-urinary symptoms dominated the clinical picture, and it was mainly on account of this that the patients sought advice. In 14 cases in the group, examination revealed a vesico-sigmoidal fistula. In 11 of the cases there was a history of bowel trouble previous to the onset of the genito-urinary symptoms. In three of the cases of vesico-sigmoidal fistula there was no history of preceding bowel trouble.

Group 5 comprised eight cases in which malignant disease was associated with diverticulitis in the sigmoid. This figure must not be taken as reflecting the frequency with which malignant neoplasm and diverticulitis are associated; it is simply a series of cases in which pathological specimens were available. Clinically, this series divided itself into two subgroups, in the first of which there was a definite history of diverticulitis going back a year or two, and in the second the diverticulitis was mild or latent, and the symptoms were suggestive of carcinoma from the outset.

Group 6 comprised seven cases which could *not* strictly be placed in any of the other groups because of atypical features. Either there was no history of constipation, or diarrhœa was a feature. In one case constipation and diarrhœa alternated. Pain might, or might not, be present, but there was a *tumour* in the left lower quadrant. In view of the fact that constipation and obstruction have been emphasised as being the natural consequence of diverticulitis, this small group of atypical cases demonstrates that there may be exceptions in which the ordinary clinical manifestations of the disease are absent.

Clinical Features of the Acute Attack of Diverticulitis (Groups 1, 2, and 3).

The cases in these three groups, about 70 per cent. of the total, were characterised by constipation and one or more acute attacks, possessing certain distinctive features which constitute a syndrome of the lower left quadrant almost pathognomonic for diverticulitis.

An attack is usually preceded for a few days by a slight increase in the degree of constipation, slight bloating in the upper abdomen with belching, and often mild rolling gas pains in the lower abdomen of momentary duration. The onset of the acute stage is often precipitated by some form of purge, or by ingestion of rough or irritating food such as fruits or vegetables. Occasionally it appears to follow exertion or straining at stool. Severe colicky pain sets in, usually in the left lower quadrant. Sometimes at the outset the pain is generalised throughout the abdomen or distributed equally through both lower quadrants, but as a rule it finally settles down in the left lower quadrant, and if it is present in both lower quadrants it is always more pronounced on the left.

The *pain* is variously described as sharp, cutting, griping, or shooting, and may remain strictly localised to the left iliac fossa or may radiate over the crest of the ilium into the left side of the back, into the left groin and testicle, or, as in one instance, into the left knee. Radiation into both testicles was observed in one case in which the pain was present in both lower quadrants. The pain is often severe enough to double the patient up; at other times he will bend over and press on the stomach for relief. This, however, is only at the outset, for if there is peritoneal involvement he finds greater comfort in complete rest. It is often severe enough to require morphine.

There is sometimes an initial chill, and then the temperature rises to 100°F. or higher. In 30 of the cases in which fever was present with acute attacks, it varied between 100° and 102°. Nausea is not infrequently present, and more rarely vomiting. Usually, however, as with appendicitis, the patient vomits once or twice only. The bowels remain obstinately constipated, no flatus is passed, and enemas administered for relief often return clear. Urinary symptoms are common. In 41 of the 100 cases examined there were symptoms referable to irritation of the bladder. Excluding for the moment the 14 cases of vesico-sigmoidal fistula which will be considered later, there still remained 27 cases in which the relationship of the acutely inflamed sigmoid to the bladder produced difficulty or inability to start the stream, urgency, frequency, nocturia, and burning pain sometimes at the beginning and sometimes at the end of micturition. In fact, some degree of vesical tenesmus is typical during an acute attack of diverticulitis. The patient frequently observes that, apart from urinary symptoms, pain is relieved when the bladder is empty.

On examination there is generalised abdominal distension, or localised fullness in the left lower quadrant. On palpation, the left iliac fossa is tender, but muscular rigidity, if present, is usually very slight. In the left iliac fossa an elongated tender tumour in the position of the sigmoid can usually be palpated. This tumour was present in 56 per cent. of the cases of surgical diverticulitis.

On account of the associated obesity, abdominal distension, and tenderness, this palpable mass in the left iliac fossa is usually best felt by the rectum or bimanually. It varies in size and shape from that of a hen's egg to that of an orange or lemon. It is smooth, partially fixed, and usually very tender. In consistency it is firm, rarely hard, and occasionally it has been mistaken for an abscess. Because of the mobile nature of the sigmoid and its tendency to form adhesions, the position of the mass, although almost invariably in the left lower quadrant, may vary somewhat. It may be accessible to the examining finger by rectum, or it may be high and far out in the left iliac fossa. Sometimes it is close in toward the median line, and may be palpated between the bladder and rectum. The most distinctive feature about the sigmoid tumour is its tendency to appear during the acute febrile period and to disappear in the intermission. The disappearance may not be complete, but there is always marked recession in size after the acute attack has passed. In some instances the patient has been the first to notice the tumour, and has not only seen the fluctuations in size during the acute attacks, but has also affirmed that the mass was larger during the present attack than during a preceding one.

An acute attack of diverticulitis may last from a few hours to two or three days. Occasionally it is prolonged for a week or more, or until relieved by operation. Defæcation usually gives marked relief, although it may be attended by considerable pain, and enemas, if persevered with, will usually relieve most of the discomfort. Occasionally slight diarrhœa may set in for a day or two, or an excessive amount of mucus may be passed. Pari passu with the relief of the abdominal distension the mass in the left lower quadrant becomes smaller and less tender, and may disappear entirely. During the acute period, from 10,000 to 20,000 leucocytes is a common finding. While it is true that in a considerable proportion of cases attacks of acute diverticulitis will abate if left alone, occasionally the obstructive symptoms are so alarming as to call for operation. In seven cases in the present series colostomy had been performed before examination at the Mayo Clinic.

Symptoms of Fistula (*Group* 4).—The symptoms referable to the development of fistula were either preceded by symptoms suggestive of a flare-up in the bowel condition or developed suddenly without any such warning. Often there was increasing constipation and intermittent pain in the left lower quadrant for a week or more. Impending perforation into the bladder was heralded by pain and tenderness immediately over the vesical area. Sometimes, however, dull and boring perineal pain was experienced for several days, and a degree or two of temperature was invariably present. Then an attack of urgent, burning, and painful micturition was accompanied by the passage of small grape-seed-like fæcal particles through the urethra and also audible gas at the end of micturition. The patient usually noticed that the urine was heavily loaded with sediment and had a fæcal odour. The passage of gas and fæces by urethra usually relieved the acute pain, but cystitis remained, resulting in urgency, frequency, and nocturia. These symptoms persisted intermittently, with occasional flaring-up of the cystitis, until relieved by operation.

Differential Diagnosis of Carcinoma (*Group* 5).—The clinical distinction between diverticulitis and carcinoma may be difficult. In fact, if carcinoma develops in a colon where there is diverticulitis, the differentiation may be well-nigh impossible, except by the pathologist, until the malignant process is advanced. Cramping pain in the left lower quadrant was usually present, but frequently burning and pain in the rectum was also complained of, and painful defæcation and tenesmus were associated features. It is true that in uncomplicated cases of diverticulitis tenesmus may occur, but it is rare, and though painful defæcation may immediately follow an acute attack, it is not present at other times. Pain and burning in the rectum are rarely met with in diverticulitis. Bleeding from the bowel is suggestive of carcinoma; it is rare in diverticulitis and, if it occurs, search ought to be made for hæmorrhoids, which are usually present as a result of the constipation. Mucus may be passed in both diverticulitis and carcinoma, but it is much commoner in the latter and is usually streaked with blood. In malignant disease pain, if present, may go through to the back, a very infrequent radiation in diverticulitis. There is usually loss of weight in both conditions. The barium enema may demonstrate a filling defect only. The sigmoidoscope will usually reveal carcinoma if the tumour is accessible, but it is rarely possible to diagnose diverticulitis in this manner.

TREATMENT.

Uncomplicated diverticula of the colon require no special treatment beyond controlling the constipation by appropriate measures which keep the diverticula of the sigmoid free, so far as possible, from the formation of hard concretions which are the precursors of inflammatory changes.

Even when inflammatory changes have taken place, the tendency is towards increasing conservatism in treatment; radical operations, implying extirpation of the affected portion of the intestine, are not to be undertaken lightly. Medical management, in a proportion of cases, not only tides the patient over an acute attack, but may even safeguard him against subsequent attacks. In severer cases, however, and when obstructive symptoms are urgent, surgical intervention may be necessary; the choice lies between colostomy, with the possibility of resection later, or resection without preliminary colostomy. The resection may take the form either of a Mikulicz operation, or an anterior tube resection of the Balfour type. In the present series, a Mikulicz resection was performed in 42 cases; in 21 an anterior tube resection was performed by the Balfour method, either with or without preliminary colostomy; in eight colostomy alone was performed. The surgical procedures carried out in the remaining cases included local excision of diverticula, resection of a portion of the circumference of the intestine, plastic closure of vesico-sigmoidal fistulæ, and short-circuiting operations to relieve obstruction.

There was a mortality of 10 per cent. Most of the remaining patients, traced for years, were relieved, but a few still had some constipation which, however, was readily controlled by paraffin.

THE TREATMENT OF DIPHTHERIA CARRIERS.

BY WILLIAM CLUNIE HARVEY, M.D. GLASG., D.P.H.,

LATE TEMPORARY ASSISTANT BACTERIOLOGIST, NORTHERN GROUP LABORATORY, NORTH-EASTERN HOSPITAL, METROPOLITAN ASYLUMS BOARD.

THE carriers from all the Metropolitan Asylums Board Infectious Diseases Hospitals were collected together in the North-Eastern Hospital and made the subject of an extensive investigation, of which the primary object was to discover why some patients should continue to harbour diphtheria bacilli for prolonged periods after convalescence from an attack of clinical diphtheria. This part of the investigation took a considerable time to complete, and the findings obtained therefrom have been published by Thomson, Mann, McCartney, and Harvey[1] in the Annual Report of the Metropolitan Asylums Board for 1926–27. The presence of pathological conditions or physical abnormalities in the nose, nasopharynx, or throat was found to be the main predisposing factor in inducing or sustaining the carrier state. It also appeared that the diphtheria bacilli were living an extra-corporeal or saprophytic existence in the inflammatory products present along with these abnormalities, and were *not* existing actually in living tissues. It followed from this that the correction of such abnormalities as enlarged turbinates, deflected septa, with crusting of the nasal mucosa and nasal discharge, and septic and ragged tonsils, ought to go a long way towards curing the carrier condition. The methods of treatment used in the investigation had therefore this object in view. The cases were all "chronic carriers," that is, people who had harboured true virulent diphtheria bacilli for a period of at least 12 weeks. This definition of a carrier, though arbitrary, was important, since it implied that the infection was not merely a transient one.

Criterion of Cure.

It was the practice at the North-Eastern Hospital to take cultures from each patient once a week, and only to regard a carrier as free from infection when six consecutive negative cultures were obtained. Very many cases, after yielding negative cultures for three, four, or even five weeks, became positive once more and remained so for prolonged periods. It is always wise to have the cultures taken by someone competent to do so, preferably the person who is to examine them. Thus at the North-Eastern Hospital all the carriers were cultured personally and were not regarded as "free from infection" until six weekly negative cultures had been obtained.

The Throat Carrier.

The carrier with bacilli in the throat only does not appear to present any difficulties of treatment. *Removal of the tonsils as first advocated by Pegler,*[2] *or of the tonsils and adenoids, gives very satisfactory results.*

At the North-Eastern Hospital 60 cases were treated by the removal of tonsils and adenoids, the operations being performed by Mr. Humphrey Marriner. Of these 60 cases 17 harboured bacilli in the throat only, and of the 17 cases 16 were cured. The remaining 43 cases had bacilli in the nose or ear as well as in the throat, and of these 19 were cured. It was noted that the percentage of "cures" decreased in direct proportion to the extent to which the nose cultures were positive. Nine patients who were operated upon because of large and unhealthy tonsils and of intermittently positive cultures showed the Klebs-Löffler bacilli in the crypts of the tonsils removed at operation, although the preceding cultures had been negative. Four nurses who harboured diphtheria bacilli in the throat had their tonsils removed before the end of the 12 weeks period which would have made them officially chronic carriers. In each case a cure resulted.

It will thus be seen that if the bacilli are confined to the throat the likelihood of a cure from removal of the tonsils and adenoids is great. The optimum time for the operation seems to be earlier than is usually advised. *If the throat cultures remain persistently positive, and if the tonsils show any evidence of being the site of an inflammatory process, they should be removed six to eight weeks after the onset of the infection.* The tonsils removed at operation were examined culturally and by section for the presence of diphtheria bacilli, which were present in the tonsils and adenoids in 61 per cent. of cases. It was evident that the tonsil likely to harbour diphtheria bacilli was not the large, clean tonsil, but the small, ragged, septic one with deep crypts. It was usually possible to foretell by clinical examination the tonsil which, on removal, would yield diphtheria bacilli on culture. In 1917 H. Stévenin,[3] and in 1921 G. H. Weaver,[4] drew attention to the fact that an attack of follicular tonsillitis in a carrier freed the carrier from infection. A. Schiotz,[5] in 1919, suggested that this observation might be applied practically by spraying the throat with living staphylococci and thus inducing an attack of tonsillitis. This method has not been tried during the present investigation, but several of the carriers in this series contracted severe tonsillitis and, although the Klebs-Löffler bacillus disappeared temporarily from the throat, it invariably returned when the acute stage of the tonsillitis had subsided.

The Nose Carrier.

Nasal carriers of diphtheria are very refractory. A constant feature is the presence of rhinitis, which may take the form of a watery or purulent discharge, or of extensive crusting round the anterior nares, sufficient in some cases to obstruct the breathing. The great majority of chronic carriers have diphtheria bacilli in the nose. Various methods of treatment have been suggested from time to time, but none has

proved completely efficient. Local application of antiseptics to the mucous membrane has never been accepted as a completely satisfactory means of treatment. Vaccines have been used by various workers,[6 7 8 9] who claim more or less satisfactory results.

At the North-Eastern Fever Hospital 38 chronic and persistently positive carriers were treated by vaccines of the organisms, other than diphtheria bacilli, present in the nose. Only in three cases were the vaccines composed solely of Klebs-Löffler bacilli. They were all autogenous. The abnormal condition of the nose was ascribed to the presence of pyogenic organisms, rather than to the diphtheria bacillus, and it was therefore hoped that, if the former were removed by autogenous vaccines, the condition of the nose would improve and the diphtheria bacilli would no longer obtain a pabulum for growth. The organisms included staphylococci (albus and aureus), pneumococci, and hæmolytic streptococci. The results were only moderately satisfactory. Of the 38 cases treated 16 cleared up after one to nine weeks. The remaining 22 cases remained positive, although some of them improved. Material from the noses of the carriers treated was inoculated on to blood-agar plates, and it was found that all the organisms from which the vaccines had been prepared had disappeared from the noses, except the staphylococci. In view of this fact a further course of treatment was sought which might be effective in clearing the ubiquitous staphylococcus from the nasal passages. This treatment took the form of a mildly alkaline nasal douche, made up as follows: sodium bicarbonate, sodium chloride, sodium biborate, aa. ʒij. to water ℥xx., i.e., about 2 grains of each per oz. of water. This stock solution was diluted for use with equal parts of warm water, and the noses were douched night and morning, the solution being allowed to run into the nose and out of the mouth by gravity. In some cases a small quantity of hydrogen peroxide (about one drachm per pint) was added to the solution to soften crusts around the nares.

The results of nasal douching were very satisfactory. Crusting and rhinitis were greatly lessened, and nasal discharge usually diminished or ceased altogether. The nasal mucous membrane became pink and healthy and altogether the condition of the nose was greatly improved. Material from the noses of the carriers thus treated was inoculated as before on to blood-agar plates, and the noses which before treatment had yielded an abundant flora were now found to be practically sterile. Moreover, although the former flora usually returned almost immediately when the douching was discontinued, the diphtheria bacilli did not do so in a large proportion of the cases.

In all 62 cases were treated. In 7 treatment had to be stopped owing to the refractory behaviour of the children. Of the remaining 55 cases 27 cleared up in from one to seven weeks. Eight cases cleared up after one relapse, and a further 8 cases cleared up after a second course of treatment. The treatment had no effect in 12 cases. Most of the children behaved quite well when being douched, and those who showed any nervousness quietened down after a short time. This form of treatment is inexpensive and easily carried out. The procedure adopted was to continue the douching until three negative cultures had been obtained at weekly intervals. Douching was then discontinued, and the carrier was discharged after a further three negative cultures, taken at weekly intervals. Thus any doubt that the negative cultures might have been due to the douching was removed. The youngest child treated was 8 months old. The complete results were :—

		Per cent.
Total cases treated	62	
Cases in which treatment had to be stopped	7	
Actual cases treated	55	
Cases cured after one course of treatment ..	27	= 49
" two courses " ..	8	= 14·5
" one relapse	8	= 14·5
Total number of cures	43	= 78
Total number of failures	12	= 22

The results obtained from douching were even better than they appear, since the carriers chosen for treatment were mostly cases who were persistently and strongly positive and who had failed to clear up after undergoing various other forms of treatment.

A method of spraying the nose with an alkaline spray was tried, but the results were unsatisfactory.

A small series of cases was treated by autogenous vaccines, together with daily nasal douching. The results in 9 cases were that 3 cleared up immediately treatment was commenced; 3 ceased to carry virulent Klebs-Löffler bacilli, but were found to be harbouring non-virulent organisms; 1 cleared up after two vaccines; and 1 failed to clear up.

A 1 per cent. solution of iodine oil was applied to the noses of four carriers. Of these three cleared up, while the other failed to do so. There was some evidence, however, that the cases were clearing up before treatment commenced, and as this form of treatment had previously been found of no avail, it was not continued.

Antrum and Adenoid Investigation.

When cases fail to clear up after vaccines and nasal douching, the antrum of Highmore was suspected as the source of the bacilli. The antrum was opened and explored in three cases. Diphtheria bacilli were isolated from it in two cases, under circumstances which excluded contamination, while in the third case the examination revealed no growth. The antrum was thoroughly cleaned out in one of the patients, and the case cleared up with the help of nasal douching. It is usually very difficult to operate upon the antra of a young child, and permission may be refused. X ray photographs are of little, if any, help. The antrum, however, should be kept in mind as a last resort in the investigation of very persistent nose carriers.

Sixteen carriers were operated upon, principally to see the effect of the removal of the adenoids upon the carrier state. In no case, however, were the adenoids removed without the tonsils, as the latter always showed sufficient evidence of abnormality or definite disease to warrant their removal. All cases chosen had strongly positive nose cultures; three of them were cured, and diphtheria bacilli were isolated from the adenoids in two of these. Removal of the adenoids does not seem to be effective in the treatment of nose carriers.

The Ear Carrier.

The treatment of ear carriers is extremely difficult. No satisfactory form of treatment was discovered. The discharge often ceased altogether for several weeks and then, without any apparent cause, began again. The commonest method of treatment was to instil hydrogen peroxide and alcohol drops into the ear. Cases were treated by vaccines, removal of tonsils and adenoids, mastoidectomy, and nasal douching. The results were as follows :—

	Cures.	No effect.	Total.
Removal of tonsils and adenoids ..	3	3	6
Vaccines (consisting of organisms isolated from the nose) ..	2	1	3
Nasal douching	3	1	4
Mastoidectomy	1	1	2
			15

Many so-called "carriers" were admitted to the North-Eastern Hospital on suspicion of harbouring diphtheria bacilli in the ear, but the bacilli were really saccharose-fermenting diphtheroids, and not true virulent Klebs-Löffler bacilli. Since these carriers are so intractable it is fortunate that the presence of virulent diphtheria bacilli in discharge from the ear is uncommon.

Results of Various Forms of Treatment.

Form of treatment.	No. of cases treated.	No. (and per cent.) of *immediate* cures.	No. (and per cent.) of *delayed* cures.*	Total No. (and per cent.) of cures.	No. (and per cent.) of failures.
Vaccines	38	10 (26·4)	6 (15·7)	16 (42·1)	22 (57·9)
Nasal douching ..	55	23 (41·8)	20 (36·2)	43 (78)	12 (22·2)
Vaccines and nasal douching combined	7	3 (42·9)	1 (14·2)	4 (57·1)	3 (42·9)
Removal of tonsils and adenoids ..	60	33 (55)	2 (3·3)	35 (58·3)	25 (41·7)

* Over three weeks and including relapses and cases in which a second course of treatment was necessary.

It should be noted that the cases chosen for treatment were the most persistent and chronic carriers obtainabl

In addition to the specific methods general hygienic methods were always adopted in an endeavour to improve the health of the carriers. It was found, however, that the general health was usually extremely good, and this factor seems to have little if anything to do with the duration of the carrier condition. Exposure to carbon arc radiation was tried, but appeared to have little effect.

Conclusions.

1. The most important carrier is the one who harbours diphtheria bacilli in the nose.

2. The only satisfactory form of treatment for the nose carrier tried during the investigation was douching with a mildly alkaline nasal douche. Properly carried out this yields excellent results.

3. Tonsillectomy yields very satisfactory results in carriers whose bacilli are confined to the throat.

4. The ear carrier, happily uncommon, is very difficult indeed to deal with, and does not respond readily to treatment.

5. The treatment of diphtheria carriers should mainly consist in rectifying local abnormalities and pathological conditions responsible for the carrier state. If this is done properly the coexistent abundant flora will be diminished, and the diphtheria bacillus will probably disappear also.

6. Diphtheria carriers should be treated as early during convalescence as is compatible with safety, always bearing in mind the likelihood of diphtheria complications. The longer the bacilli are allowed to remain in the infected area the more difficult does their removal become. In addition, apart from the loss of education to the children, the burdens which diphtheria carriers lay upon the finances of the various public health bodies make the necessity for their early treatment and cure a very important consideration.

I wish to thank Dr. F. H. Thomson, medical superintendent of the North-Eastern Hospital, and Dr. J. E. McCartney, director of research and pathological services to the Metropolitan Asylums Board, for their unfailing courtesy and assistance throughout the investigation.

CARDIAC INFARCTION WITHOUT PAIN.

A SERIES OF EIGHT CASES.

BY C. F. T. EAST, M.D. OXF., F.R.C.P. LOND.,
JUNIOR PHYSICIAN, KING'S COLLEGE HOSPITAL; PHYSICIAN, WOOLWICH WAR MEMORIAL HOSPITAL;

C. W. CURTIS BAIN, M.B. OXF., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, HARROGATE INFIRMARY;

AND

FALKLAND L. CARY, M.B., B.CH. DUB.

ALTHOUGH the syndrome of cardiac infarction with prolonged anginal pain is now well recognised, few cases have been recorded of infarction without pain. We have recently seen seven cases where the patient was able to refer the beginning of his illness to a particular day on account of the sudden onset of severe dyspnœa, but this was completely free from pain.

CASE 1.—A police sergeant, aged 57, enjoyed good health until February, 1926, when he suffered from an attack of "influenza" characterised by dyspnœa and giddiness. He recovered completely from this and, save for a slight degree of shortness of breath when bicycling, his health remained perfectly normal during the rest of the year. On June 29th, 1927, he "caught a cold," and was confined to bed on account of great dyspnœa and a severe cough. He recovered rapidly, but the dyspnœa persisted and became more troublesome, so that he experienced considerable difficulty in walking even on the level, and required four pillows for comfort at night. During the last three weeks he had noticed that he was passing less urine. He had not had any pain.

Examination on Jan. 17th, 1928, showed a large heavily built man who appeared distinctly pale. The pulse was 134 and regular. The arteries were not thick; blood pressure 140/90. The apex of the heart was in the sixth space and 1 inch external to the nipple. The impulse was moderately heaving in character. The first sound at the apex was short and was reduplicated from the nipple line to the sternum. There were no murmurs. There was no œdema; the liver was not enlarged, and the lung bases were clear. The urine contained no albumin. The Wassermann reaction of the blood serum was negative. The electrocardiogram showed a left-sided preponderance.

He was put to bed and given digitalis, ♏xx., four times daily for eight days, followed by ♏xxx. daily. During this period his pulse fell to 80, and his urine output increased from 20 oz. before treatment to an average of 40 oz. All trace of the reduplication disappeared. On Feb. 10th he died suddenly in bed.

Post-mortem Examination.—The right side of the heart was engorged with blood, but appeared healthy. All the valves were normal. The cavity of the left ventricle was considerably reduced by the presence of ante-mortem clot, which was firmly adherent to the cardiac wall. This clot was distributed in two irregular areas, the first and larger of which involved the apex, while the second started posteriorly in the region of the papillæ of the mitral valve, and traversed the ventricle horizontally, ending near the interventricular septum. Corresponding to this distribution of the clot there was extensive disease of the muscular wall. At the apex it was almost wholly replaced by dense white fibrous tissue, so that only a thin strip remained on the pericardial surface. In the second area fibrosis was not so advanced, but was evident as a belt encircling the ventricle. Histological section showed that the clot was firmly organised to a thickened endocardium. The proximal 2 inches of both coronary arteries were thickened, atheromatous, and partly calcareous. The left contained a strip of active ulceration and destruction of the intima. There was complete occlusion of the following vessels: (1) a large branch of the left coronary, descending in the anterior interventricular sulcus to the apex, and a small branch of this supplying an area in the region of the interventricular septum; (2) two large branches of the right coronary, from a clot lodged at their bifurcation, supplying the posterior wall of the ventricle and extending round to the anterior surface as far as the interventricular septum. This was an abnormal distribution, since this area is usually supplied by the circumflex branch of the left coronary. Sections of the four occluded arteries showed a trace of lumen in each. In two of these multiple channels could be seen. The cellular structure of the tissues occluding the vessels suggested organised clot rather than inflammatory endarteritis, so that it appeared as if partial recanalisation had occurred (Fig. 1).

CASE 2.—A male, aged 51, a patient of Dr. Williamson, had enjoyed good health until December, 1927, when he "caught a cold" after a strenuous day. For this he had to go to bed for a few days as he was so short of breath; and during this time his ankles were swollen and he had a troublesome cough. He recovered rapidly, but his dyspnœa persisted so that he has not felt quite right since. On Feb. 7th he spent the day motoring, and caught a further "cold," which kept him in bed till the time of examination. He had the same symptoms as before, with the addition of some tightness at the lower end of the sternum, which he attributed to coughing.

Examination on Feb. 17th, 1928, showed a large man who appeared rather pale. His arteries were only moderately thickened; blood pressure 160/110. The pulse was 100 and irregular from frequent extrasystoles. The apex of the heart was in the sixth space and external to the nipple, and the impulse was slapping in character. The second sound was reduplicated from the apex to the sternum. There were no murmurs. Œdema was present over both ankles, and crepitations could be heard at both bases. A polygram (Fig. 3) showed a low-tension pulse with a moderately persisting alternation, and ventricular extrasystoles.

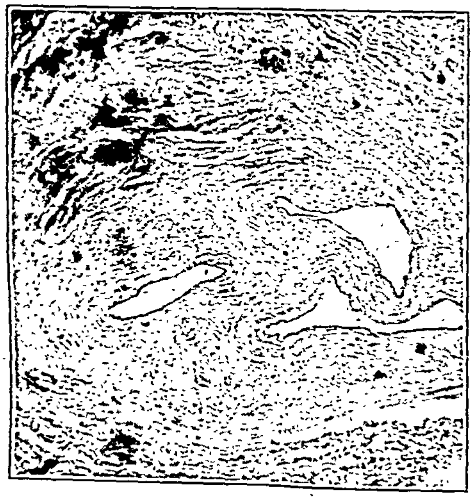
Ten days later he had symptoms of infarction in the lungs, with pain in the right side of the chest and hæmoptysis. He recovered from this, and is now free from all signs of heart failure.

Although post-mortem evidence of infarction is lacking, his condition was so exactly comparable to the other cases that it can hardly be doubted that he has one or probably two infarcts in his myocardium.

CASE 3.—A man, aged 54, a patient of Dr. Hinsley Walker. Four years ago, after rapidly mounting two flights of stairs to his room, he grasped the bed rail and fell on his back with his "face working." A doctor pronounced the condition to be a faint and kept him in bed the next day. Since that time he has been in good health, but he noticed he could not manage the long walks he used to take, as he became short of breath. During the last six months he has had a cough and some nocturnal attacks of dyspnœa, with tightness round the lower part of the chest. Deep cyanosis had been noticed when he was turned on his left side to reduce prolapsed hæmorrhoids.

Examination on Feb. 28th, 1928, showed a big man whose face was cyanosed. His pulse was 120, and his blood pressure was 160/110, but these readings must be discounted to a certain extent, since the patient was apprehensive. The radial artery was impalpable. The apex of the heart was half an inch outside the nipple line. The first sound at the apex was replaced by a systolic murmur which was conducted out to the axilla. The second sound and the sounds at the base were normal. The lungs were normal except for a few rhonchi posteriorly. The liver was not palpable and there was no œdema.

FIG. 1 (Case 1).



Section of terminal anterior branch of left coronary artery, showing recanalisation in granulation tissue of organised thrombus.

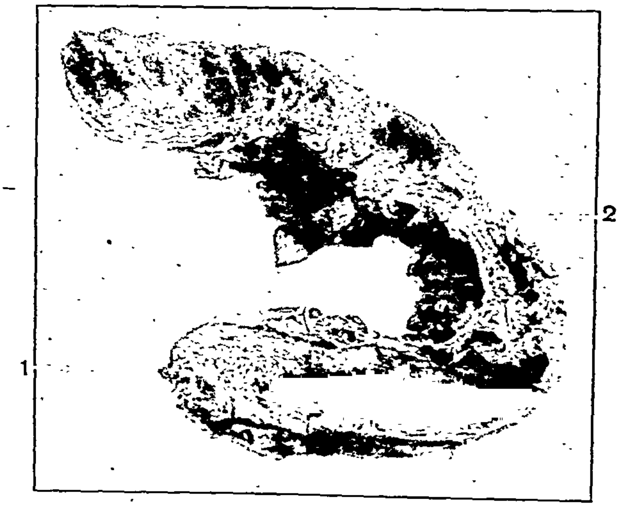
A fortnight later he had a hæmoptysis and became feverish. Three days after he died suddenly.

Post-mortem Examination.—Both auricles and the left ventricle of the heart were much enlarged. There was no valvular disease, but the mitral orifice was greatly dilated. The anterior surface of the left ventricle near the apex was firmly adherent to the pericardium by a dense fibrous strand with an area of attachment of about 1¼ inches in diameter. This area formed the apex of a spherical aneurysm of the ventricle approximately 2 inches in diameter. The wall of the aneurysm was thin and calcareous, and contained little muscular tissue. The lining endocardium was yellow, thickened, calcareous, and partly ruptured by ulceration. The left coronary was in a condition of advanced atheroma throughout its course, with ulceration and calcification. The main branch, descending along the anterior interventricular sulcus, was completely obliterated by old organised tissue. The terminal portion of this branch was patent but collapsed. The right coronary was normal except for some ulcerative atheroma in its proximal portion. At the apex of the left lung there was a necrotic area where the lung was firm and solid. On section all this area was seen to be involved in an acute necrosis which was breaking down into pus. The main branch of the pulmonary artery supplying the apical region was plugged with a thrombus for about one inch, and the thrombus had extended into the branch supplying the remainder of the upper lobe where the lung had a normal appearance. There was a bilateral pleural effusion, some ascites, and a nutmeg liver.

The patient appeared to have had two pulmonary infarcts. The first caused the hæmoptysis and the lung abscess, while the second was followed by sudden death.

CASE 4.—A man of 63 was in good health until July, 1926, when he had a sudden and severe attack of dyspnœa, which obliged him to keep to his bed for two months. He recovered to a certain extent, but could never go back to his work, and a year later he was admitted to King's College Hospital. He had not had any pain.

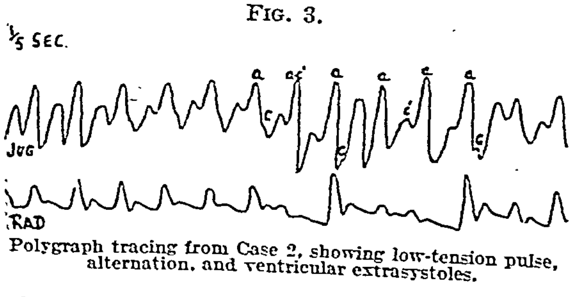
FIG. 2 (Case 1).



Slice of left ventricle in lateral plane, showing two main areas of fibrosis: (1) apex; (2) middle transverse zone cut at two points.

On examination he was slightly cyanosed and the legs and lower part of the body were swollen. The pulse was irregular from extrasystoles. The blood pressure was 162/116, and the radial artery was thick. The apex-beat was almost imperceptible, but the heart appeared to be enlarged in both directions. The first sound at the apex was reduplicated, and there were soft systolic murmurs in the mitral and tricuspid areas. The liver was large and tender. The urine contained albumin, and the blood-urea was high, 145 mg. per 100 c.cm. The electrocardiogram showed a left-sided preponderance with an inverted T wave in lead I, and a flattened T in lead II. The P.R. interval was increased to 0·24 of a second. Extrasystoles were present, arising from the right ventricle and from an intermediate focus near the septum. For a time he improved under treatment, but later heart failure supervened, and he died 15 months after his initial attack.

FIG. 3.



Polygraph tracing from Case 2, showing low-tension pulse, alternation, and ventricular extrasystoles.

Post-mortem Examination.—The heart was very large; on the anterior aspect of the left ventricle near the apex the pericardium was adherent to the chest wall. Corresponding to this was an area of fibrosis in the ventricle where the muscular wall was thin. This extended into the adjacent part of the right ventricle and into the lower and anterior part of the septum, and was continuous with a mural thrombus which was firmly attached to it. Inside the right ventricle was a recent thrombus, and there were some infarcts in the lungs. The anterior descending branch of the left coronary artery was in a state of advanced atheroma, but the main channel seemed to be patent as though it were recanalised. Microscopical section of the infarct showed that the muscle was replaced by fibrous tissue and that the small arterioles were obliterated by overgrowth of their intimal coats.

CASE 5.—A man, aged 52, had a sudden and severe attack of shortness of breath in September, 1926. He had previously enjoyed good health. This dyspnœa affected him apart from exertion, and he was completely incapacitated. At the same time a troublesome cough developed, and he experienced paroxysmal attacks which he called asthma. After about a month he recovered sufficiently to be able to work a little in a warehouse. He soon had to give up, however, and came into hospital. At no time had he had any pain in the chest.

On admission he was orthopnœic and pale, with a little cyanosis. The pulse was irregular from frequent extra systoles, the radial was moderately thick, and the blood pressure 140/90. The heart was considerably enlarged, and the apex beat was wavy. There was reduplication of the first sound at the apex, and an apical systolic murmur. The jugular veins were full, the liver was large and tender, and the ankles were swollen. The electrocardiogram showed left bundle branch block with premature beats arising in the left ventricle. The Wassermann reaction was negative.

During two months in hospital on digitalis and diuretin he improved considerably. Heart failure recurred, however, and he died suddenly in hospital 11 months after his original attack.

Post-mortem Examination.—The heart weighed 750 g. All the chambers were dilated and the walls of the ventricles were abnormally thick. Under the posterior flap of the mitral valve the endocardium was thickened, and the trabeculæ were thin and atrophic. The posterior papillary muscles were wasted. Fibrous tissue replaced the muscle for a depth of 2 mm. This area of fibrosis involved the upper part of the posterior wall of the left ventricle and extended forwards into the posterior part of the interventricular septum so that it encroached upon the left branch of the bundle of His. The coronary arteries were calcified in places, the circumflex branch of the left coronary and the posterior part of the right being the most severely affected. Both arteries, however, had their main channels patent. There was a patch of thickened pericardium over the area of infarction at the back of the left ventricle.

CASE 6.—A man, aged 41, had an attack of breathlessness when walking in the street. He was quite overcome and had to keep to his bed after it for some days. After a little he recovered fairly well and was able to get about again. Then gradually the breathlessness on the least exertion came back. When seen he was obviously far gone in heart failure. The condition was in striking contrast to his appearance eight months before, when he had been successfully treated for gastric ulcer. The heart was greatly enlarged, with a wavy, heaving apex-beat. A clear gallop rhythm, due to reduplication of the mitral first sound, could be heard at the apex. There was severe venous engorgement. Under treatment with large doses of digitalis he got rather better and insisted on leaving hospital. In a month he was back with thrombosis of the right subclavian and jugular veins, and his heart was worse than ever. On this occasion it was possible to take an electrocardiogram. This showed small complexes in all leads, absence of the T wave in the first lead, with very small indefinite T waves in the other two. Frequent extrasystoles came from several foci in both ventricles.

The Wassermann reaction was negative.

The diagnosis was thrombosis of the coronary arteries and myocardial infarction.

He gradually got worse and died, about six months after the onset of the symptoms.

Post mortem there was a very large heart with a patch of thickening of the pericardium over the left ventricle in front. Here the wall was very thin, and on opening the chamber a large area of infarction was revealed. This involved most of the front of the left surface of the interventricular septum and a good deal of the front of the left ventricle itself. The descending branch of the left coronary artery was blocked by an old thrombus just at its origin. At this point there was a small atheromatous patch. The obstruction was not more than a centimetre long, and obviously canalised, as it was easy to demonstrate that blood could be squeezed through small holes in the obstruction. Elsewhere there was very little atheroma. The changes of chronic venous engorgement were intense. The right subclavian and innominate veins were thrombosed, and there were sundry infarcts in the lungs.

CASE 7.—A professional man of 68 was walking in his garden when a sudden shortness of breath overcame him, so that he collapsed and seemed for the time as though dying. Before this he had been active and had played golf a good deal, doing rather more than usual for his age. After the attack he could not leave his bed. The dyspnœa continued so that he had to keep sitting up, and was really most comfortable in a chair. When seen a fortnight after the attack he looked blue, the legs were swollen, and the liver large. The heart beat at 84, with many extrasystoles. The radial was rather tortuous, the blood pressure 125/70. Over the heart, which was a good deal enlarged to the left, the mitral first sound was faint, and then reduplicated, so that a gallop rhythm was heard. Under fairly large doses of digitalis and diuretin he made progress and is now a good deal better.

There can be little doubt that in this case myocardial infarction led to this sudden and severe failure of the heart, the chief symptom of which was dyspnœa, without anginal pain at any time.

CASE 8.—A business mar [illegible] and retired to bed. When [illegible] sat up with a cry, and fel [illegible] not been looking well for some months, and for the last five months had complained of getting tired very easily. Every day he had walked up a considerable hill on his return from business. Angina he had never had, neither was he troubled with dyspnœa to any degree. He had not consulted a doctor for five years.

Post mortem there was an area of infarction in the upper part of the front of the left ventricle. It was old and well organised, and had evidently been there for months. Thrombosis had occurred in the descending branch of the left coronary artery, but small canaliculi were easily seen in the obstruction where the thrombus had been. The heart was very large, 26 oz., with dilated capacious chambers. In the aorta there was much soft atheroma, the radial was thick and tortuous, and the kidneys rather granular. It is probable that he had high blood pressure. The striking point here is the negative history, there being neither angina nor dyspnœa coming in an attack, nor the gradual onset of heart failure. Yet the lesion was a large one, of some considerable standing.

Discussion.

Parkinson and Bedford,[1] in their account of cardiac infarction, include a type with dyspnœa and failure but without pain, which may be found when infarction supervenes in a patient with pre-existing signs and symptoms of heart failure. Two out of their 100 cases were of this type. Gibson,[2] out of 43 cases verified by post-mortem examination collected from the literature, has a group of six patients with chronic heart failure in whom dyspnœa was a prominent symptom. J. Cowan, quoted by Gibson, referred to two cases in which there was a sudden onset of dyspnœa, but in one there was a coexisting parenchymatous nephritis, while the other subsequently developed pain. Coombs[3] had a case in which there was a sudden onset thought to be due to influenza, and death occurred in three months from heart failure. Wearn,[4] on the other hand, found dyspnœa to be prominent in 16 out of the 19 cases of infarction studied by him. It was the predominant sign and chief complaint in four of these patients who had no previous signs of cardiac failure, and was so severe that it was out of proportion to the other findings in the heart and lungs.

Six of our cases are clinically very similar. They all had a sudden attack of severe dyspnœa associated with heart failure. Recovery from this illness took place to a greater or lesser extent, but in no case was the patient ever the same as he was before the attack. In three the recovery was rapid and fairly complete; in the others it was the prelude only to a slowly progressive and fatal heart failure. The physical signs were such as have been described after cardiac infarction accompanied by pain. There was enlargement of the heart to the left, and a form of gallop rhythm at the apex. Five cases had frequent extrasystoles. In three instances the electrocardiogram showed that they were arising from the region of the heart in which the infarct was subsequently found. In the third case the polygram demonstrated the presence of pulsus alternans. Case 3 was seen four years after the probable date of his initial attack, at a time when he was not suffering from any cardiac embarrassment; his death was not primarily due to heart failure.

It appears, therefore, that cardiac infarction may occur in an apparently healthy individual, entirely unaccompanied by pain. It should be suspected as the cause of an attack characterised by the sudden onset of severe dyspnœa with heart failure, when no other reason can be found. The signs of failure may disappear fairly soon, but some permanent disability is always left.

We are much indebted to Dr. F. B. Smith, pathologist to the Harrogate Infirmary, for the post-mortem notes of Cases 1 and 3, and for his care in preparing the photographs; and to Dr. Raymond Crawfurd for permission to include Case 4.

RADIOLOGY AND SURGERY IN CANCER OF THE BREAST

AND IN "CHRONIC MASTITIS."

By J. H. DOUGLAS WEBSTER, M.D., M.R.C.P. EDIN.,

PHYSICIAN IN CHARGE OF THE RADIOLOGICAL DEPARTMENT, MIDDLESEX HOSPITAL.

ANALYSIS of 600 cases of breast cancer, treated with X rays or radium, and 60 cases of "chronic mastitis," treated with X rays, suggests that both in the prevention and cure of cancer of the breast radiological measures could be employed with advantage much more extensively than they are at present. Their use is almost entirely restricted now to practically hopeless patients with inoperable primary or recurrent disease, as it was for so long in cancer of the uterus, and there is little recognition of the unique effect of radiation (1) in rendering cases on the borderline of operability operable, (2) in sterilising the operation area so that so-called "recurrences" are less likely to take place, (3) in being a complete method in itself leading to cure in a proportion of early and even advanced stages of breast cancer, and (4) in its almost invariable success in the precancerous "chronic mastitis."

"Recurrence" and Preoperative Radiation.

If in all clinically early patients the malignant disease were localised in the breast substance, the percentage of surgical success would be 100 per cent. That the results as a whole are much poorer than this shows that in no given patient can the limitation to the breast be affirmed with absolute certainty. John Fraser has shown with whole-breast sections what widespread changes may occur with a small apparently early tumour: and for many patients we must fear, as Sir Lenthal Cheatle has said, that "when a lump appears in carcinoma the disease is well advanced."

When the second stage with palpable axillary nodes is reached, we may only reasonably expect from purely surgical intervention a 1 in 25 chance of saving life. Many sets of statistics support this conclusion of James Ewing. In these more advanced cases life may be prolonged for many years by surgical measures, but surgical statistics do not show what happens in the large proportion of interventions in which operation is incomplete. If the operation is gravely incomplete it may be followed by rapid widespread local or general recurrences within a few months, as I have seen in about ten patients who had had *no* radiation. It is such patients that suggest that there may be a "growth-restraint" exercised by the primary focus, the removal of which, with its possible growth-restraining hormones, leads to rapid new growth in the residue of cells. Alternatively these cases suggest that the knife, cutting across infected tissues and setting free live cancer cells, has stimulated their growth-activity—as incision is one of the best means of stimulating an animal tumour's growth (W. E. Gye). (Claude Regaud and James Heyman have shown in the tongue and cervix respectively that diagnostic incisions are contraindicated, as they make the end-results worse.)

In view of the large body of pathological and clinical evidence as to the partial or complete sterilising effect of radiation on malignant cells, a widespread preoperative use might well be made of X rays or radium to sterilise the operation field as far as is practicable. Very little advantage has, however, been taken of this means, which seems not far from ideal for the purpose. All that I have been able to find advanced in opposition to a general use of preoperative radiation is (1) that it is an uncertain and insufficient measure (F. C. Wood is against it because, on the basis of some animal experiments and contrary to a vast body of clinical experience, he asserts that a four or five skin-erythema dose is necessary to destroy breast cancer cells); (2) that its use delays the healing of the skin incision—N. S. Finzi has noted cases where this has happened; and (3) that radiation may stimulate the growth, as Sir Holburt Waring concludes from one case where a patchy redness and skin nodules appeared a fortnight after one X ray application. But the very existence of a stimulation dose is wholly denied by many radiologists of great experience (Guido Holzknecht, Heyman). A moderate surface application should not interfere with the healing of well-nourished skin-flaps, as has been shown by several of my own preoperative cases. While surface radiation cannot be relied on to cure with one application or set of applications a large tumour occupying most of the breast substance, it can be relied on with a great measure of probability to render no longer viable isolated groups of cells in lymph nodes and channels, and, in short, to sterilise the dangerous outlying field of the operation, when a movable small breast tumour has not already advanced beyond the early stage of axillary invasion. I have had about ten preoperative patients whose operation took place from three days to some months after the X ray application; in none of them was there faulty skin-healing of the scar. The cases were clinically so diverse that it is difficult to draw more conclusions than that (1) operation-scar healing is not delayed when the dose is adequate but not excessive; (2) some Stage I.–II. cases show three-year freedom from recurrence with preoperative and no post-operative radiation; and (3) some Stage II.–III. cases were made operable, and showed no local recurrence, although some died of metastases.

B. J. Lee and R. E. Herendeen have reported results with 92 patients showing the percentages alive and well in three years: after surgery alone, 24 per cent.; after post-operative radiation, 39 per cent.; and in those who had both pre- and post-operative radiation, 52 per cent. This illustrates the advantages of a combined method over surgical removal alone. They advise operation three or four weeks after the X rays; if it is performed earlier there may be hyperæmia. Neumann, F. Sluys and Coryn report good results from a rather similar combined technique (40 cases).

Radiation after Recurrence.

When "recurrence" has taken place, the results of X ray or radium treatment differ greatly according to the factors (some still undetermined) of site, type of growth, state of the patient, and method of radiation employed. The earliest noted "recurrences," those of pea or millet-seed size in or near the line of the scar, almost invariably disappear after surface X rays or radium. Larger nodes frequently become no longer palpable, or leave a small residue, after surface radiation with or without buried radium. My three-year "cure" of major recurrences, mostly supraclavicular or intercostal, on 165 cases with deep X rays or radium, is 22 per cent. One illustrative case may be summarised:—

CASE 1.—Aged 46; radical operation elsewhere, June, 1923. No post-operative X rays. By October, 1924, a massive scar recurrence, roughly 4 by 2 inches, and a ¼ inch thick, a nodule close to the sternum, glands in both axillæ, and in the right supraclavicular triangle. One high-voltage X ray course over these areas, followed on the scar area by a well-marked reaction, Grade I. All signs of disease disappeared after this, and the patient remains in good health. As prophylactic, a gland in the opposite axilla was treated in August and October, 1926, and a doubtful recurrence, a small tender right supraclavicular gland, was treated in October, 1927. There is now no sign of disease.

For patients with as widespread recurrence as this, X ray treatment is the more suitable. For a localised recurrence, for example in one supraclavicular triangle, half a gramme and upwards of radium element has been applied in a number of patients externally. The best results appear when the radium has been applied for suberythematous doses from 6 centimetres' distance in a "double-strength" intensity. Where a change is made from radium to X rays or vice versa, owing to an insufficient result, care must be taken not to overdose, as skin damage may result, with consequent bacterial infection and renewed growth of the residue. In no breast case has lung induration or severe blood damage been a result of treatment.

Post-operative Radiation.

Because in any given patient an incomplete operation may have been performed, some surgeons make a practice of referring patients for a "prophylactic" course of X rays. Analysis of 208 cases shows what wide variations there are in the state of the patient at the time of operation, the clinical and histological type of the growth, the method of operation, and other factors. It is safe to say that local scar recurrence can be almost completely abolished when patients have a post-operative course of X rays beginning within three or four weeks at latest after the operation. But in a considerable number of patients referred later than that, and in nearly a third of all this post-operative series, early signs of local recurrence in or near the scar, or in the axillary, parasternal, or supraclavicular glands, have been found when they were examined every six or eight weeks in the following year or two years. This shows the high proportion of incomplete operations, and the need for repeated examinations in the years following operation. If this were done in all patients after operations for malignant disease the end-results would be much better, for in almost every one of these breast cases, where definite or suspicious recurrences were noted at their earliest stage, further and more active radiation to that area has been followed by the disappearance of all signs of disease. The most lamentable cases seen, perhaps, by radiologists are those where breast or cervical operations have been followed by massive and practically hopeless recurrences; had the condition been recognised months before they would almost certainly have been curable.

Where the operability rate is high, and many of the patients are in Stage II. at operation, as at the Middlesex Hospital, the results of operation followed by a medium-voltage X ray course for one or two years, as shown by Sampson Handley's and some of G. Gordon-Taylor's figures, are approximately a 47 per cent. three-year freedom from recurrence. Handley has lately shown that in his Stage I. cases, with parasternal radium insertion and post-operative X rays, there has been 85 per cent. of "cures." Where operation is admittedly incomplete—i.e., where the axilla could not be cleared completely, or "recurrence" is evident a few weeks after the operation—the value of post-operative radiation may be demonstrated perhaps most conclusively. I have had 26 of these patients, all of whom were promptly treated with high-voltage radiation to the axilla and supraclavicular triangle; eight, that is, just under a third, showed no recurrence after two years. Without radiation it is not probable that so large a percentage would remain without signs of disease. Several patients have lived for over five years after growth was left adherent to the axillary vein, or was evident in the supraclavicular triangle at the operation or within a few weeks. An illustrative case may be summarised:—

CASE 2.—Aged 49; underwent radical operation in August, 1925, by Mr. E. L. Pearce Gould; the axillary vein could not be cleared completely. Four series of high-voltage treatments to the axilla and medium-voltage to the supraclavicular and scar areas followed. In February, Mr. Pearce Gould suggested that the treatment might be stopped. By October there were enlarged supraclavicular glands, which disappeared after two high-voltage treatments.

In April, 1927, there were two recurrent nodules in the line of the scar, which by June were no longer palpable after further high-voltage treatments. The patient remains free from signs of recurrence. This case shows the advisability of high-voltage supraclavicular applications in doubtful cases at least, and the inadequacy of an *incomplete* medium voltage X ray course to prevent the appearance of secondaries in the line of the scar. The full course is two years with ten treatment courses; this patient had three only; recurrences 9 and 15 months after.

Primary Cancer of the Breast.

(1) *Inoperable.*—About one-third of all patients coming with breast cancer to surgeons come in an inoperable stage, and for these much can be done by judicious irradiation; the ulcers heal, the cutaneous and deeper nodules disappear, and the arm becomes more movable and less swollen. Some patients may be rendered operable, and for these excision by the diathermy knife is especially suitable. Of 86 advanced inoperable patients the results have been satisfactory for more than a year in only about 10 per cent., as chest and other metastases become evident in so many patients and overshadow the breast condition. It has been found impossible to estimate beforehand, without actual trial of radiation, how any given patient will respond, and for this reason it is worth while commencing the treatment of many apparently hopeless cases, as a few will be markedly benefited. S. E. Pfahler and B. P. Widmann report in their series an average duration of life of five years and one month, as against two and a half to three years in untreated cases. An inoperable case well after 11 years may be summarised:—

CASE 3.—Aged 62; sent for X ray treatment by Mr. Sampson Handley in 1917, as there were too many axillary glands for operation. In April, 1922, the right breast showed nipple retraction as it had for years, but was otherwise satisfactory; there was a rather large right axillary gland, a small hard one in the left axilla, and one in the right posterior triangle. More X ray treatment was given. Seen at intervals since, there is no sign of disease, and the patient is in very good health.

(2) *Operable.*—I have now had 20 patients with operable breast cancer treated with X rays or radium or both, in all of whom operation had been refused, or was considered inadvisable. I am satisfied that radiation is a justifiable alternative to operation, as with radiation alone the percentage of success closely approximates to surgical results, and is at present rather better. Of my operable series published two years ago[1] (excluding two cases dying of intercurrent disease, one who discontinued treatment, and the fixed ulcerated case classed as "inoperable" when she began radiation treatment), there is a 75 per cent. three-year "cure" of Stages I. and II., and a 100 per cent. "cure" of Stage I. These percentages of results with X rays and massive surface radium are similar to those of Hermann Wintz and of Pfahler in their operable series treated by X rays; as radiation results they are only likely to be equalled by radium needle insertion methods such as those of Neumann, Sluys and Coryn, and of Geoffrey Keynes.

"Chronic Mastitis."

Much attention has been drawn lately to "chronic mastitis" as a precursor of cancer, and clinical observations have been confirmed by Bagg's work on breast functional activity and on milk-retention in mice after parturition, which produced cancer in a large percentage of nursing animals after duct ligature. Also the work of A. Rosenberg on the menstrual breast has important bearings on the subject (see below). Sir Lenthal Cheatle has drawn a clear picture of the comparison between the successive changes in the skin resulting from tar-painting, and the changes in the breast terminal ducts and acini of degenerative hyperplasia, cystic retention, papillomata, and final malignancy. A similar series of changes has been lately described in the colon. It is a reasonable deduction that the effective treatment of "chronic mastitis" will, in at least some cases, prevent the appearance of carcinoma. Little is known, however, about the beneficial effect of X rays on mastitis. The literature refers only to success with acute mastitis, as with other acute inflammatory conditions, and of a number of surgical authorities consulted Handley alone has been found to recommend X rays before operation in cases not responding to simpler measures.[2]

---

[1] THE LANCET, 1926, i., 431.

I have had 60 of these "chronic mastitis" patients, and in over 90 per cent. the result has been perfectly satisfactory after, as a rule, about four medium or high-voltage treatments by cross-firing the breast. One or two have been operated on for large painful breasts, or for continued neuralgia-like sensations, and of those traced only one has been operated on for malignant change. This supervened a year after medium-voltage treatment to a large breast had been stopped. High voltage would have been better for such a large breast.

In this series of "chronic mastitis" were six or seven who had been sent as cases of doubtful "early carcinoma" in the larger nodules. As Ewing reports a carcinoma of 2 millimetres in size in a patient 21 years old, there may have been other cancers in the series! These results are, from all preventive points of view, noteworthy, and should be emphasised in any comprehensive campaign against cancer. It is an unfortunate tradition among patients that anything wrong with the breast probably means an operation, and I am convinced from many inquiries that the fear of operation is largely responsible for the high percentage of patients who come for treatment not in an operable stage, much less a "mastitis" stage, but in a frankly inoperable and, so far as we know as present, a practically hopeless condition.

Artificial Menopause as an Aid.

X ray castration has been recommended by several radiologists in every case of breast cancer. This procedure has recently received evidence in its favour on the histological side by Rosenberg, Polano, Berberich, Loeschke, and others. They have shown the remarkable proliferation of acini which takes place in the breast monthly and regresses in the intermenstruum. That a similar proliferation of cancerous epithelium takes place monthly has not yet been proved, as far as I know, by animal experiments. John Fraser, however, in a personal communication, writes that he has several specimens in his possession which suggest that the carcinomatous change receives a definite stimulus at the menstrual period, although he does not regard the matter as proved. I have seen patients whose recurrences were doing very well under radiation treatment suddenly flare up when menstruation began after a stoppage of some months. Such cases suggest strongly, on the clinical side, that it might be well to consider as a routine the production of an artificial menopause in all breast cancer patients who have not already reached the natural menopause. I have thus treated six advanced patients as a late resource. Advocated by Sir George Beatson, oöphorectomy has been found by Sir Holburt Waring to be of marked temporary service in about 30 per cent. of patients. As the X ray menopause can be induced in the great majority of patients in one to three hours with a minimum of disturbance, it is suggested that this is a matter which urgently requires discussion as a neglected but possibly valuable factor in the general treatment of cases, whatever local method be employed.

Conclusions.

1. It was once true, but is true no longer, that the only chance for the patient with cancer of the breast is early operation.

2. By radiological methods alone, or as the main treatment, results are being obtained in cancer of the breast similar to those in cancer of the cervix: a certain percentage of inoperable cases are cured, and the results in the operable group are rather better than those from surgery alone.

3. Combined methods of radiation and operation offer a fruitful field for further advances. The radiation artificial menopause is a little used but possibly valuable auxiliary treatment.

4. Radiological methods simulate and also encourage the natural attempt at cure, usually seen only in isolated subcutaneous nodules, by causing degeneration of the malignant cells and arousing a lymphocytic and connective tissue reaction. Experimentally, radiated areas have shown an immunity to tumour implantation; this is an additional argument in favour of pre- and post-operative radiation. The tumour bed and adjacent lymphatic glands appear to be stimulated (Douglas Quick and Max Cutler: in neck cases).

5. Operative removal is sometimes followed by the rapid growth of previously latent secondaries, possibly by loss of a "growth-restraint" of the primary (Ewing). For this reason, among others, conservative radiation methods may prove to be on the whole better, in some forms of cancer at least, than radical operation.

6. Experimentally and clinically the best way to stimulate a growth appears to be to cut into it. Clinically this has been seen in sarcomata, the inflammatory type of breast carcinoma (acute carcinoma incised by mistake for mastitis with immensely rapid growth following), and other carcinomata. (For inflammatory breast cancer radiation offers the only hope: Lee and N. E. Tannenbaum.)

7. In the hope of avoiding a considerable percentage of "recurrences" after incomplete operation, there is a very strong plea to be made out for invariable pre- and post-operative radiation of the operation area and the adjacent lymphatic drainage areas.

8. The present-day surgery of cancer may be said to be in a pre-Listerian stage. A new axiom might well be formulated and acted upon; no operations should take place on live unsterilised tumours.

9. The ideal method is for all new patients with malignant disease to be seen by the surgeon and radiologist in consultation. This was done at the Middlesex Hospital for some time by the late Mr. T. R. Kellock.[3] As a rule, however, the purely surgical view prevails, and radiotherapy is considered merely as an adjuvant to surgery—to be employed only when surgical means have failed, as surgery was once regarded by medicine. Sir Henry Gauvain has lately suggested how prejudicial to the public interest this segregation of radiological departments from the full clinical stream must be. Radiotherapy has become a new specialty of method, and there is much to be said in favour of giving the radiologist, as a cancer therapist primarily, a status of real equality with his other hospital colleagues, and the charge of a department with out-patients and beds, like that planned for Prof. Gösta Forssell in Stockholm—a 50-bed clinic in the new Serafimer Hospital.

If the voluntary hospitals, with their many other commitments, can make no full provision for advanced X ray and radium therapy in cancer, it is to be hoped that the Ministry of Health will initiate or support any movement for cancer clinics throughout the country (as in France) where the possibilities of radiotherapy may be fully explored. The annual mortality from breast cancer is about 5000, a thousand more than ten years ago in England, and surgical technique has been perfected for so many years now that there is not likely to be much lessening of the mortality unless expert radiological methods are more extensively employed than they are at present.

[3] THE LANCET, 1922, i., 552.

NEW BRIXHAM HOSPITAL.—Earl Fortescue, Lord Lieutenant of Devon, has opened a new hospital at Brixham, the gift of Mr. Charles Hellyer. There are 12 beds and two cots equally divided between the male and the female sides, and four private wards.

THE SACRO-ILIAC PROBLEM.

By C. B. HEALD, C.B.E., M.D. Camb.,
M.R.C.P. Lond.,

PHYSICIAN TO THE ELECTRO-THERAPEUTIC DEPARTMENT, ROYAL FREE HOSPITAL; CONSULTANT IN ELECTRO-THERAPEUTICS, ROYAL AIR FORCE MEDICAL SERVICE.

Whether or not the sacro-iliac joint is ever liable to disabling displacements in the absence of severe trauma has been the subject of much discussion from time to time. Warm support has been given to the claim that manipulation, with or without strapping, cures or rapidly alleviates the distressing symptoms. These same claims have been equally warmly rejected. In the group of cases which form the subject of this report three factors have been constantly present.

(*a*) A history of relatively sudden onset of pain in the back following a muscular movement of the "surprise" type, and quite insufficient to cause a dislocation of a joint the size of the sacro-iliac synchondrosis.

(*b*) An inability to cough without pain and without accentuating all symptoms.

(*c*) A complete inability (not necessarily on account of pain) to lie flat on the back and lift both legs (when separated by about six inches) simultaneously off the ground with the knees fully extended.

All the patients have been more uncomfortable in a sitting position, or when passing from this to standing, than when fully erect. The majority also have been unable to roll in bed towards the affected side without a spasm of radiating pain.

A medical man who has suffered from this distressing condition described his history and symptoms to me in detail as follows:—

"At the time of the onset I was just recovering from a rather prolonged and debilitating attack of bronchitis. One morning, when sitting at stool, I was seized with a more than usually severe bout of coughing and suddenly 'felt something give' in the region of the left sacro-iliac joint. There was no pain. Nor was there any pain to speak of on first standing, only a vague discomfort. Very shortly after I bent to pick up a small bag, weighing a few pounds, and my return to the standing position was accompanied by an almost intolerable hot and stabbing pain which radiated down from the original spot to the back of the knee and left the whole of the back of the left thigh with a woolly, heavy feeling. Walking was not painful, only uncomfortable, and a limp did not develop until later. Work and duty could be carried out, though with a sense of insecurity. After some two weeks of this condition the stabbing attacks disappeared, leaving a continuous 'lumbago' backache with the whole of the left leg feeling heavy and somewhat unmanageable. At this stage the ilium, where it abuts on the sacro-iliac joint, felt more 'lumpy' than on the unaffected side. I was told, though personally I was unaware of it, that my trunk was no longer erect, but bent forward and to the left. The nearest approach to a comfortable position was standing with the left leg behind and the shoulders thrown back. Diathermy, ionisation, ultra-violet light, and radiant heat gave only temporary benefit."

When examining this patient I noticed for the first time a curious sign—namely, that while he could lie on his back and lift each leg with the knee straight without difficulty or pain, he appeared to have absolutely no power to lift both legs together. It was not a question of impending pain; he simply might have been paralysed for this particular movement. Passive movements without an anæsthetic, radiant heat, and strapping effected a reasonably rapid recovery.

Since then I have come to recognise that the double-leg-lifting test is important in distinguishing one group of "backache" cases from all others. It has been possible to collect a considerable number of these cases, both in hospital and private practice, and they all conform so closely to the first that it will be sufficient to give brief notes of two or three.

Case 1.—A man, aged 26, was in a motor collision on May 4th, 1927, but was not turned over or thrown out; he thinks he swung suddenly to save himself from impact. He complains of pain deep in the left flank. Coughing hurts and shoots pain down the distribution of the left sciatic nerve. X rays show no bony injury or abnormality. On examination, single-leg-lifting is difficult, but can be carried out. Attempted double-leg-lifting produces no movement whatever of either leg—"no pain, just can't do it." Gripping the iliac crests, so as to close them up, immediately makes it possible to commence this movement. Pressing the iliac crests apart produces the same pain as coughing.

Treatment.—Absolute rest in bed, anodal galvanism, massage, movements, and gradual re-education effected complete recovery for general office work in three to four weeks, but a ban was put on rowing races.

Case 2.—A married woman, aged 54, tried to lift a bed on Dec. 5th, 1927. Two or three hours later she noticed pain low down on the left side of the back. Sneezing and coughing were most painful; in some positions—e.g., getting in or out of a bath—acute pain radiated over the buttock. Rest in bed, ionisation, massage, and hot baths for a week did no good. When seen on Dec. 15th examination was very difficult on account of rolls of loose fat all round the loin, &c. Double-leg-lifting was, however, impossible and separating the iliac crests made any effort to raise the legs more difficult, while closing them made it possible to move the legs slightly.

Treatment.—Direct current was administered and the patient wore a corset with a pad of wool while resting in bed, with a pillow under the buttock. Massage was given, at first avoiding all passive movement. By Christmas Day the patient was well enough to go into the country and recovery was uninterrupted.

Case 3.—An unmarried woman, aged 42, complained of pain in her back six and a half years ago. This definitely began after lifting a child aged 4 and running with her; she "felt something go" on the left of the spine, and has felt pain at intervals ever since. "I may go for weeks and months without discomfort, then a slight something sends a stab of pain down the left of my back and for a time after this any movement causes excruciating pain." When seen on March 7th, 1927, she stated that while changing her frock for dinner she had felt something click, with slight pain which afterwards gradually increased until at 9 A.M. she was completely incapacitated. Double-leg-lifting was impossible. Single-leg-lifting caused no difficulty and there was very little difference between the sound (right) side and the painful side.

Treatment.—Strapping, accompanied by Bristow coil treatment to all the muscles in the region of the left sacro-iliac joint, rapidly made the patient well, and by learning how to use the apparatus on herself she has been able to keep well.

The next case illustrates another aspect of this interesting group.

Case 4.—A woman, aged 38, on trying to stand on her hands in January, 1924, "ricked her back" and ricked it again the same evening while dancing; this was followed immediately by pain in the back, made worse by any forward-bending movement. Coughing was painful except in the full knee-bend position, and pain could be diminished by holding something in front of her (in effect fixing the ribs, see later). On April 2nd, 1925, she caught a "chill" in church and then the pain returned, only worse, and went down the legs in a spasm. A celluloid corset, partially immobilising the sacro-iliac joints, was a great help.

Case 5.—A man, aged 22, strained his back wheeling a barrow in June, 1927. There was no slip or sudden emergency and he went on working after the pain began. He got well, but when skipping in September, 1927, the pain returned down the right leg and was also felt on sitting or coughing. On Dec. 20th, when first seen by me, this pain was still present and prevented all games. The X rays were normal. The double-leg-lifting sign was present and hypertension of the thighs relieved the pain. In the forward-lying position the iliac side of the sacro-iliac joint on the affected side appeared to project more prominently than on the healthy side. As this asymmetry largely disappeared after treatment, it is worth noticing, particularly as it has been noted in other cases. Treatment was carried out, as described below for the more severe and long-standing cases, and recovery has proceeded satisfactorily.

Case 6.—A woman. The original injury was caused by turning to the left and leaning over to lift a coal scuttle; the right foot slipped on some grease and a feeling of something that "went" in her back was followed some days later by a disabling pain in the back and down the left thigh. In this case, rest in bed, strapping, and jackets only effected temporary improvement. On examination in the forward-lying position the sacro-iliac joint on the injured side was so loose that Mr. J. Cunning considered it justifiable, after all other methods had failed, to fix a screw through the joint. This he carried out successfully on Jan. 17th, 1923, and the patient was able to resume her duties as cook-general and has carried on successfully ever since. An X ray of the sacrum taken on Feb. 14th, 1928, by Dr. Bertram Shires showed the screw in its original position.

The strength of the vaccine was 1 mg. per c.cm. There was no apparent result save that the granulations of both operation wounds increased greatly and became very vascular. Twelve minims were injected on August 12th. and the granulations were painted with a mixture of brilliant green and methyl-violet in equal parts of a 5 per cent. solution in alcohol, and the abscess cavity was packed with strips of gauze soaked in the same solution. One c.cm. of the vaccine was given on August 24th, and it was decided to abandon the large doses of iodide preparations which she had been having by mouth, as *during the whole of the* illness no intravenous injections could be made owing to the fact that it was found impossible to distend any of the superficial veins sufficiently, and it was of course impossible to suggest cutting down on veins for this purpose.

No progress was made up to Sept. 17th, when she was seen by Sir Chartres Symonds. There was then bulging in the side behind the first operation wound and it seemed likely that another abscess was forming in this position. It was decided to continue the vaccine treatment and await further developments. Twenty minims were given on Sept. 28th and 22 minims on Oct. 1st, and on the latter date the temperature reached normal for the first time since April, and after Oct. 7th showed no evening rise. The granulations had by this time completely disappeared, leaving a healthy sinus from front to back and the swelling in the side was much smaller. The vaccine was injected weekly until the end of October, and, subsequently, fortnightly. The sinus had closed by Nov. 4th and vaccine treatment was continued at monthly intervals until June. 1927.

She is now in perfect health and able to carry on her duties as a masseuse.

Notes on Bacteriology by DR. BRAXTON HICKS.

On May 28th I received from Mr. Turner some pus and three pieces of tissue. After prolonged search through several smears of the pus, a few filaments and one mass of streptothrix were encountered, and rapid sections of the three pieces of tissue showed streptothrix in only one. Attempts to cultivate the streptothrix failed.

Mr. Turner asked my opinion as to the possible success of an autogenous vaccine, as the patient's condition was desperate. Recovery has been recorded even with a stock actinomycotic vaccine, for the difficulty in providing an autogenous vaccine arises from the inability to induce the streptothrix to grow on artificial media in every case. However, some fresh pus having been sent by Mr. Turner on July 30th, a fairly abundant growth of the streptothrix was obtained in glucose broth under anaerobic conditions (Mackintosh and Fildes jar). Subcultures (fortunately *luxuriant*) were only obtained on the first occasion, all attempts to raise a second series failing. After centrifugalising down from the broth cultures, the streptothrix was washed several times in saline. The supernatant saline was removed from the last washing as far as possible to the last drop, the resultant wet mass being ground up in a small sterile agate mortar. This squeezed out a certain amount more fluid, which was dried off in an oven, taking great care not to dry out the mass completely. A slightly moist mass resulted, which could be weighed, and an original stock suspension was made up of a strength of 1 mg. per c.cm., of which the patient had an initial dose of 0·05 mg. in August. Later on (October), in the course of the disease, the stock was increased to 4 mg. per c.cm.

In discussing the part the vaccine played in this case it must be remembered that the patient had many lines of treatment going on at the same time. I have seen a number of cases of streptothrix infection of abdominal and thoracic regions, *but I do not* remember to have seen one clear up on iodine or iodides. These always are, and should be, tried. The brilliant green and methyl-violet mixture kept the wound clean and lessened the exuberance of the granulations, but there is evidence that the vaccine clinched the cure. Soon after the vaccines were started the granulations became vascular and large, and I think that was a sign of progress in healing, for the granulations in streptothrix are not particularly vascular. Moreover, in the latter part of September, a swelling was developing *in the region* of the original operation wound. At this time the vaccine had been pushed up to 1 mg. of the streptothrix mass and immediately after this dosage had been reached the temperature began to reach normal and the swelling to subside. The increase in the dosage was continued systematically and carefully, until she was taking 4 mg. of the *streptothrix mass*, so apparently large doses are easily tolerated.

A CASE OF

POST-VACCINAL SEROUS MENINGITIS.

By F. E. SAXBY WILLIS, M.C., M.D., M.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF OUT-PATIENTS, ROYAL CHEST HOSPITAL AND HAMPSTEAD GENERAL HOSPITAL.

ALTHOUGH a number of cases of encephalitis and myelo-encephalitis following vaccination have now been reported, chiefly in the French literature, meningitis in this connexion seems to be a rare complication, and the following case may therefore prove of interest.

A school-boy, aged 11, was admitted to the Weir Hospital, Balham, on May 20th, complaining of headache, pain in the neck, and drowsiness. A fortnight before admission he had been vaccinated against small-pox. A week later he had complained of headaches and pain in the neck, becoming semi-comatose two days previous to admission.

On admission he was drowsy but irritable, and could be roused. Four pustules were present on the left arm. Nothing abnormal could be found in the heart, lungs, or abdomen. In the central nervous system, apart from the drowsiness, no definite abnormality could be detected at first, but by the fifth day general hypertonus had developed and Kernig's sign was present. The knee-jerks were not obtained, the plantar response was doubtful on the right and extensor on the left. There were no ocular palsies, and the fundus occuli was normal in each eye. Fever was present (102° F. on admission, falling to normal by the third day). Lumbar puncture was performed on May 20th, and fluid withdrawn under considerable increase of pressure. The latter was reported on as follows by Dr. Mary Schuster:—

> "A water-clear fluid, with little deposit after centrifugalising, cells 50 per c.mm.; small mononuclears, 65 per cent.; large mononuclears, 30 per cent.; polymorphonuclears, 5 per cent.; a few red cells; sugar diminished in amount; chlorides, 0·67 per cent. (diminished); albumin, 0·03 per cent.; organisms: cultures sterile, no tubercle bacilli found; Wassermann negative."

On May 26th considerable improvement took place, and by June 8th the patient was quite bright mentally and had no symptoms. By this date the reflexes were normal and the patient was apparently fully recovered. He was discharged on June 10th.

In my opinion the clinical features, with the definite increase in the cell content of the cerebrospinal fluid, place this case in the category of what Stiner refers to as "serous meningitis" rather than of an encephalitis.

DONATIONS AND BEQUESTS.—Mr. and Mrs. J. B. Crichton, of Luthriebank, near Cupar, have given £10,500 to meet the cost of the upkeep of Adamson Cottage Hospital, Cupar. Mr. Crichton recently gave £5000 to the hospital. —Dr. R. Tudor Williams, who was drowned recently while bathing at Villerville, France, left the following legacies to North Wales Institutions: £500 to the Carnarvonshire and Anglesey Infirmary at Bangor, and £100 to each of the following: Llanfairfechan Nursing Association, Leeswood (Mold) Nursing Association, Caergwrle and Hope Nursing Association, Tryddyn (Mold) Nursing Association, Caergwrle Presbyterian Church, and Horeb Chapel, Llanfairfechan. —Miss Lucy Prince-Smith, Bournemouth and Staintondale, Scarborough, besides many other bequests, left £10,000 to the Royal United Kingdom Beneficent Association for general purposes, £2000 each to the Leeds General Infirmary, the Royal Victoria and West Hants Hospital, Bournemouth, the Royal National Sanatorium, Bournemouth, and the Victoria Hospital, Keighley; £500 to the Driffield Cottage Hospital, £1000 to Dr. J. Nicholson Dobie, of Keighley, and subject to certain other bequests, the residue of her property equally between the Leeds Infirmary, St. Catherine's Home, Bradford, the Royal Victoria and West Hants Hospital, Bournemouth, the Royal National Sanatorium, Bournemouth, and two other institutions.—An anonymous donor has given £1000 to the University of Manchester to be applied for general purposes as the council may determine.

Reviews and Notices of Books.

THE ROBERT JONES BIRTHDAY VOLUME.

A Collection of Surgical Essays. London: Humphrey Milford, Oxford University Press. 1928. Quarto. Pp. 446. £2 2s.

LAST week we reported the presentation of this volume at a dinner given to Sir Robert Jones by the authors of the essays contained in it, including the preface by Sir Berkeley Moynihan, and an appreciation by Sir John Lynn-Thomas. With the exception of the first article by Mr. Muirhead Little, which treats of the history of orthopædic surgery, all the essays are on clinical orthopædic subjects. The list of contributors of these, which includes five distinguished foreign specialists as well as one Canadian, is in itself evidence of the value of this volume as a serious contribution to orthopædic surgery. The editors tell us in a prefatory note that the idea of this book originated among Sir Robert's friends on the Council of the British Orthopædic Association, and that the 24 authors were selected from among his personal friends, those American and continental surgeons who had come under his influence chiefly during the war, and those British surgeons who have worked under him in the military orthopædic and pensions hospitals. A glance at the names of these writers prepares the reader for much interesting and instructive matter; it is proposed here to give in a bare outline some idea of their merits.

Prof. Osgood, of Boston, heads the list of foreign contributors with an essay on the frequent association of intestinal stasis with spinal sacro-iliac arthritis, a topic which is much thought of just now. The cases recorded fully justify the hypothesis implied in the title. Dr. Murk Jansen, of Leyden, has a reputation as a surgical pathologist which will suffer no diminution from a study of his paper on dissociation of bone growth. Prof. Putti, of Bologna, contributes a paper on two cases of tumour of the femur, which admirably exemplifies his resourcefulness and skill in bone-grafting. Prof. Nathaniel Allison, of Harvard, discusses open operations for congenital dislocation of the hip. Although he admits that manipulative reduction often gives good functional results, he prefers the security of a reconstructed acetabulum when risk of ankylosis is avoided by preserving the capsule. The same subject is dealt with by Prof. Hey Groves, who, however, is more optimistic as to the results of manipulative reduction in patients not too old. Dr. Jacques Calvé, of Berck-Plage, treats of a rare affection, infantile vertebral osteochondritis which he first described in 1924. The condition is of some importance, as it may be mistaken clinically for Pott's disease, unless radiographs are truly interpreted. This article, which is in French, is well illustrated with X ray pictures. Prof. Clarence Starr's short essay on acute infections of bone drives home the lesson that osteomyelitis should be detected and treated much earlier than is as yet usual. Mr. R. C. Elmslie's work on fibrocystic disease of bones is well known, and his words here add to our knowledge of the subject. Radiology has enormously increased our knowledge of ossification of the skeleton and its anomalies or rarities. Dr. Thurstan Holland's paper on the accessory bones of the foot conveys the results of great experience in this field, and is a valuable guide in the differential diagnosis between injury and abnormal development. Mr. Brownlow Mitchell, of Belfast, explains the mechanism of the production of spiral fractures and discusses their treatment. His X ray pictures show excellent results. The subject of peripheral nerve complications of fractures and dislocations of the elbow is an important one, for, as Mr. Harry Platt says, they may be the grounds for unfavourable criticism of the surgeon and even actions at law. The careful study of his paper should make such misfortunes rare—this is a very thorough paper. The president of the British Orthopædic Association, Mr. H. A. T. Fairbank, gives us a well-documented and reasoned essay upon infantile cervical coxa vara. Mr. McCrae Aitken writes on curvature of the spine. Mr. Rowley Bristow on cysts of the semilunar cartilages of the knee, the pathology of which he discusses thoroughly, and the same subject is touched on by Mr. S. Alwyn Smith in sidelights on knee-joint surgery. Mr. Blundell Bankart contributes a short but practical paper on dislocations of the shoulder-joint, including all its forms and ætiologies. Sir W. I. de C. Wheeler writes judiciously of bone-grafting in advanced cases of Pott's caries, and gives a table of the results in a consecutive series of 30 adults. Adult cases of Pott's disease are notorious for their high death-rate, but Sir William Wheeler only lost six of this series, one of whom, moreover, survived six years. Mr. G. R. Girdlestone's paper on arthrodesis and other operations for tuberculosis of the hip, and that of Mr. Laming Evans on astragalectomy are worthy of their position in the volume. Mr. Naughton Dunn on arthrodesis of the tarsus for foot deformities and Mr. W. H. Trethowan on fracture-dislocation of the ankle-joint deal with subjects of which they are acknowledged masters.

We have spoken with uniform praise of the contributions, and the high standard reached by them shows that all the writers considered the occasion as one in which they should put forth their best. The volume is well got up and fully illustrated, and any profits from its sale will be given to Sir Robert Jones for the funds of his scheme for the care of cripples.

HISTORY OF MEDICINE.

Storia della Medicina. By ARTURO CASTIGLIONI, Professor of the History of Medicine, University of Padua. Milan: Società Editrice "Unitas." With 389 illustrations and 3 colour plates. Pp. 972.

As the standard Italian histories of medicine were published over 60 years ago, and were even then incomplete, there was obviously need for a book to carry on the story and incorporate the results of recent research. It is peculiarly appropriate that the long record of medicine should attract Italian students, for nowhere else do past and present so meet and mingle as in Italy. From the busy streets of Milan one may step into the vast Ospedale Maggiore, founded in 1457 and still little changed since the seventeenth century, with its huge wards that have never lacked patients through the centuries. And in Siena it is even more striking to cross from the cathedral, with a constant stream of tourists pouring into it from luxurious motor-cars, and enter the great Hospital of Sta. Maria della Scala, founded in the eleventh century as a refuge for pilgrims as well as a hospital, where Santa Caterina laboured from day to day and S. Bernardino ministered to the victims of the plague in 1400, and where, out of an entrance hall frescoed by Sienese primitives, one passes at once into operating theatres and laboratories equipped with the latest inventions of medical science.

Of late years medical historians have been busy, and have gathered a rich harvest, and now the English reader need be at no loss for information, both authoritative and attractively set forth. Italy, with her awakened energies and self-consciousness, is leaving no field untilled, and it is fitting that, from her ancient and honourable University of Padua, Prof. Arturo Castiglioni should send out this stately and well-illustrated volume, in which the history of medicine is followed down to our own time. To cover so rich a field the author has, of course, been obliged to omit much; but he has arranged his material skilfully, and the significant peaks in medical history stand out clear, and the thread of interest is continuous and absorbing.

For English readers the most useful parts of the volume will be those wherein the achievements of Italians are described with legitimate pride—especially the later chapters in which the long succession is approve of birth control because they are dominated by ego-instincts. No suggestion is made as to why one instinct should predominate over the other in a given individual, and the remedy proposed by Dr. Eder as a solution of the conflict may strike the reader as banal. "Education," it is said, "is the weapon with which such *opposition is to be fought*." While both books may well be of interest to lay readers, it does not seem likely that they will prove very informative to members of the medical profession.

This statement, however, does not hold of the third book under review. The author of "Parenthood: Design or Accident?" is a medical man writing under a pseudonym, and the book fulfils a real need. The author clearly has had considerable experience of contraceptive methods, and his little book is compact and relevant. Its most valuable feature is the comparative treatment of the indications for the use of different contraceptive methods, and this book may be recommended as containing one of the most impartial and balanced discussions of the practical and technical aspects of birth control that has yet appeared from the pen of a medical writer.

The standpoint from which the last book of the series is written, and also the motive which inspired the author to write it, are summarised in the following sentence of the preface:—

> "From the correspondence that has been printed in the various London journals during the last two or three years, it would appear that there is a large body of public opinion in this country which, although not resting on the foundation of any religious orthodoxy, is strongly opposed to birth control, and it is partly with the view of providing those who represent this body of opinion with as complete a statement as possible of the case against the new teaching, and also of giving them an alternative solution, that this work was undertaken."

From the outset, therefore, the book compels attention. The criticisms of birth control here advanced do not emanate from a theological assumption as to the nature of God's will, nor from a biological dogmatisation as to what is and is not "natural." They emerge from certain sociological, psychological, and medical considerations for which much interesting evidence is adduced. The essential thesis of the book is the contention that by modern contraceptive methods good stocks are eliminated as much as, or even more than, bad ones. The reduction of the birth-rate is achieved at the expense of valuable, rather than of useless, strains. The selection is blind. Birth control is a process of night-hoeing, in which the wheat is likely to be cut down with the tares. The author argues that the problems of over-population and degeneracy are intimately linked with one another, and that any reduction of the population which, in the future, may prove necessary should first and foremost be a purgation of degenerates. And the author outlines a policy to guide us in such a purgation. Of the books written in recent years against the practice of birth control this is by far the best. The author has been at pains to acquaint himself with the voluminous literature which the subject has now acquired, and he writes with a trenchant lucidity which makes his book a pleasure to read.

AN APPROACH TO WINGED FLIGHT.

By JOHN D. BATTEN, M.A. Brighton: Dolphin Press. With photographs. Pp. 78. 5*s*.

THIS little book contains much new and original information and is illustrated by eleven photographs and ten line drawings which render the exposition clear. Mr. Batten begins by pointing out the essential difference between the flight of insects and that of birds, it being the latter with which his experiments are concerned. In many birds, especially the larger birds such as the albatross and the condor, flight is attained by keeping the wings almost stationary on the principle of gliders. This suggests that the pectorales majores exert almost entirely a *postural activity*, their function being to keep the wings from flapping upwards, just as the chief function of the quadriceps extensor is, not to extend the knee, but to keep the knee from bending. Mr. Batten has found that a twisted skein of natural silk, as obtained from the cocoon, forms an exceedingly strong and light spring to maintain the wings of his model horizontal. A four-skein torse of 23 in. span twisted by a rod or lever in the middle will sustain a boy "weighing 8 st. 2 lb. hanging by his hands 2 ft. 6 in. out along the lever" which is then horizontal. If desired the mere weight of the man could maintain the wings horizontal, but this appears to be more than is required.

In the tentative model (Photos. VI. and VII.) the man's hands grasp two levers controlling the two wings while his feet rest on a firm base board. When his knees are slightly flexed, the wings are horizontal, by pulling against the base board and extending his knees, as in rowing, the wings are depressed, and on bending his knees and relaxing his muscles the wings are raised. The upward movement of the wings will occur from the fall of the body between the wings when the pressure of the air will raise them. If the rhythmic movement be in the same phase and of the same period as the oscillation period of the wings, the wings can be flapped with very little exertion and practically no fatigue. Great attention has been paid to the problem of rising easily from the ground, and also to that of landing.

The book contains valuable suggestions for all who are interested in the problem of flight.

JOURNALS.

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol. XXV. April–June.—Dr. C. P. Symonds contributes a critical review on encephalitis periaxilis diffusa—Schilder's encephalitis. He states that until the publication of papers by Bouman, and Collier and Greenfield in 1924 this disease was unknown except to a few neurologists. It usually occurs in children and young subjects without any obvious cause. The onset lasts a few days and the course is progressive with some remissions to a fatal issue after a duration ranging from a few months to three years. The chief early sign is cerebral blindness, which is followed by mental impairment and increasing spastic paralysis. The condition is usually bilateral but may commence on one side or be confined to one side. The disease may begin in the occipital lobes or in some other part of the brain. In several cases a familial incidence has been noted, which is in favour of an infective cause such as neuro-syphilis, or indicates inherited abiotrophy. Post-mortem examination shows areas of softening in the central white matter of the affected lobes. Histologically, there is general infiltration of the brain with round cells engaged either in the removal of myelin or the formation of glia fibrils. The vessels are surrounded with fat-laden granule cells, phagocytic cells of glial origin, and small round cells of the size and shape of lymphocytes.—In a paper on Hemiplegia associated with Extensive Nævus and Mental Defect Dr. T. Brushfield and Dr. W. Wyatt describe the pathological changes found in the cases of which they had previously related the clinical features. They conclude that the paralytic manifestations may be ascribed to the presence of intracranial nævi and the mental defects only partly to this cause, as they found a definite under-development of the neurones throughout the brain.—Dr. Eric Pritchard reports an Atypical Case of Achondroplasia, illustrated by skiagrams, and comparable to the atypical forms found in animals such as pug dogs.—Dr. Kaj. H. Baagoë, of Copenhagen, records his Investigations on the Pirquet and Wassermann Reactions in Asthmatic Children. From examination of 83 asthmatic children, aged from 2 to 15 years, he found that a positive Pirquet reaction was not more frequent than among ordinary hospital children, thus confirming Wallgreen's view that there is no ætiological connexion lymph-nodes, small and not painful, and easily rolled about under the fingers, is never present in scarlet fever." The description of the chicken-pox eruption is disappointing and the diagnosis of this disease from small-pox, as set out, does not sufficiently emphasise the importance of the distribution of these eruptions. The lesions of small-pox are here stated to be uniform in size; this is not our experience, nor is the prodromal scarlatiniform rash of chicken-pox as rare as he implies. The life of the rubella rash is described as follows: "It fades, first, on the face after two or three days, and then over the rest of the body, and the entire period of the eruption does not last over three or four days." It is correct that the eruption first fades on the face, but it is unusual for it to persist there even for two days, or for the eruption to remain on any part of the skin surface more than 72 hours after its appearance. Dr. Shaw tells us death is almost certain in septic or malignant cases of scarlet fever. That death is almost certain in malignant scarlet fever all will admit, but though the fatality rate is high, recoveries from the septic form are not uncommon.

These small criticisms are called for in case of a further edition appearing, but on the whole the information supplied is reliable and clearly presented, while the book gives in convenient compass much information of interest to the practitioner. It is well printed, beautifully proportioned, and sufficiently illustrated. Three coloured plates show the Dick reaction, the Schick reaction, and diphtheria membrane. These are all very good, and the illustrations of severe pharyngeal diphtheria and typical tonsillar diphtheria are particularly worthy of praise.

An interesting introductory chapter is supplied by Dr. Edward S. Godfrey, Director of the Division of Communicable Diseases, on the responsibility of the attending physician in cases of communicable diseases, and the chapter on tuberculosis in children is by Dr. William E. Lawson, physician-in-charge, Albany Hospital Tuberculosis Sanatarium.

MEAT INSPECTION.

The Principles and Practice of Meat Inspection. By GERALD LEIGHTON, O.B.E., M.D., D.Sc., F.R.S.E., Medical Officer (Foods), Scottish Board of Health. London: W. Hodge and Co. 1927. 25*s.*

THE book is divided into two parts: Part I. dealing with General Principles, and Part II. with Regional and Special Meat Inspection. Part I. includes accounts of methods of inspection, of meat and its characters, of the lymphatic system, and of the general pathology, parasitology, and bacteriology of meat inspection, with chapters on Abattoirs and Slaughter-houses and on Methods of Slaughtering, the latter taking up no less than 34 pages. The last chapter in Part I. is entitled Judgment and Condemnation, and it is unfortunate that its ten pages should be confined to the Scottish instructions and the English recommendations. This chapter might have been amplified with advantage and have included a discussion of the scientific grounds for these official recommendations, since many difficulties arise in practice and the subject is of great importance.

Part II. is a clear and valuable account of the different abnormal conditions which may be found. The arrangement is a little difficult to follow, since one chapter deals with one disease (tuberculosis), the next with diseases in one animal (swine), while of the following chapters some deal with special organs and others with special regions (thorax and abdomen). Thus tuberculosis of the pig is discussed in one chapter while paragraphs on tuberculosis of swine are found elsewhere. Two useful sections are devoted to edible fish and inspection of fish, while notes on inspection of game and poultry are also included. The term "meat inspection" in this volume is used in a very limited sense. Very little is said about the characteristics and inspection of imported meat; the large and important subject of made-up meat foods is entirely ignored, while reference to canned foods is confined to a quotation from an American paper on the examination of spoiled canned foods, which is mainly a discussion of laboratory methods and gives no help in practical inspection work.

The book is for the most part a guide for the meat inspector working in public abattoirs or slaughter-houses. Good advice is given for the detection of gross pathological lesions, but while this is the most important aspect of the practical work of an inspector the value of the microscope and of other auxiliary methods of investigation deserve his attention. Such methods stimulate interest, advance knowledge, and supply additional proof in cases which come before the courts. The author does point out that "a standard text-book on bacteriology should always find a place on the meat inspector's book-shelf," but he does not emphasise the fact that the trouble of taking it down from the shelf and studying it will be rewarded. The illustrations are numerous and for the most part excellent.

BIRTH CONTROL.

Some More Medical Views on Birth Control. By Eleven Contributors. Edited by NORMAN HAIRE, Ch.M., M.B. London: Cecil Palmer. 1928. Pp. 239. 7*s.* 6*d.*

Medical Help on Birth Control. By Fourteen Contributors. London: G. P. Putnam's Sons. 1928. Pp. 225. 6*s.*

Parenthood: Design or Accident? By MICHAEL FIELDING. London: Labour Publishing Company. 1928. Pp. 96. 2*s.* 6*d.*

The Night Hoers. By ANTHONY LUDOVICI. London: Herbert Jenkins, Ltd. 1928. Pp. 288. 7*s.* 6*d.*

THE first of these books is produced as a counter to a book, edited by Sir James Marchant, and reviewed in THE LANCET, 1927, i., 1165, the tone of which was unfavourable to the practice of birth control. Dr. Haire points out that not one of the eight contributors to Sir James Marchant's book appeared to have had any considerable experience of contraceptive practice. He also states that the average age of these eight contributors is 62, and suggests that their views may not be representative of the medical profession—particularly of its younger elements—as it exists to-day. The second book is offered to the public in response to the statement recently published in the *Church Times*—viz., "the public has a right to expect better guidance from doctors than it gets at present in this matter." Both books, therefore, consist of a collection of essays written, with two exceptions, by medical men or women favourably disposed to the practice of contraception. They are intended for the general public Comparatively little is said about the purely medical aspects of this question. Religious, ethical, and sociological arguments, most of which have been used before, are advanced with a considerable amount of repetition. To those acquainted with the literature of the subject, the most interesting essay is that appearing in the second book, by Mr. Warren R. Dawson, entitled "Early Ideas upon Conception and Contraception." This contributor adduces new evidence as to the practice of contraception by the early Egyptians. A novel point of view is that propounded in the first volume by Dr. M. D. Eder, writing upon the subject of the psychology of birth control. This essay does not contain, as might have been hoped, an account of the psychological effects of the various contraceptive practices upon different people. It is concerned with an exposition of the psycho-analytic theory of why people approve or disapprove of birth control. According to this theory, people disapprove of it because they are animated by "life instincts." And people approve of birth control because they are dominated by ego-instincts. No suggestion is made as to why one instinct should predominate over the other in a given individual, and the remedy proposed by Dr. Eder as a solution of the conflict may strike the reader as banal. "Education," it is said, "is the weapon with which such opposition is to be fought." While both books may well be of interest to lay readers, it does not seem likely that they will prove very informative to members of the medical profession.

This statement, however, does not hold of the third book under review. The author of "Parenthood: Design or Accident?" is a medical man writing under a pseudonym, and the book fulfils a real need. The author clearly has had considerable experience of contraceptive methods, and his little book is compact and relevant. Its most valuable feature is the comparative treatment of the indications for the use of different contraceptive methods, and this book may be recommended as containing one of the most impartial and balanced discussions of the practical and technical aspects of birth control that has yet appeared from the pen of a medical writer.

The standpoint from which the last book of the series is written, and also the motive which inspired the author to write it, are summarised in the following sentence of the preface:—

> "From the correspondence that has been printed in the various London journals during the last two or three years, it would appear that there is a large body of public opinion in this country which, although not resting on the foundation of any religious orthodoxy, is strongly opposed to birth control, and it is partly with the view of providing those who represent this body of opinion with as complete a statement as possible of the case against the new teaching, and also of giving them an alternative solution, that this work was undertaken."

From the outset, therefore, the book compels attention. The criticisms of birth control here advanced do not emanate from a theological assumption as to the nature of God's will, nor from a biological dogmatisation as to what is and is not "natural." They emerge from certain sociological, psychological, and medical considerations for which much interesting evidence is adduced. The essential thesis of the book is the contention that by modern contraceptive methods good stocks are eliminated as much as, or even more than, bad ones. The reduction of the birth-rate is achieved at the expense of valuable, rather than of useless, strains. The selection is blind. Birth control is a process of night-hoeing, in which the wheat is likely to be cut down with the tares. The author argues that the problems of over-population and degeneracy are intimately linked with one another, and that any reduction of the population which, in the future, may prove necessary should first and foremost be a purgation of degenerates. And the author outlines a policy to guide us in such a purgation. Of the books written in recent years against the practice of birth control this is by far the best. The author has been at pains to acquaint himself with the voluminous literature which the subject has now acquired, and he writes with a trenchant lucidity which makes his book a pleasure to read.

AN APPROACH TO WINGED FLIGHT.

By JOHN D. BATTEN, M.A. Brighton: Dolphin Press. With photographs. Pp. 78. 5s.

THIS little book contains much new and original information and is *illustrated* by eleven photographs and ten line drawings which render the exposition clear. Mr. Batten begins by pointing out the essential difference between the flight of insects and that of birds, it being the latter with which his experiments are concerned. In many *birds*, especially the larger birds such as the albatross and the condor, flight is attained by keeping the wings almost stationary on the principle of gliders. This suggests that the pectorales majores exert almost entirely a *postural activity*, their function being to keep the wings from flapping upwards, just as the chief function of the quadriceps extensor is, not to extend the knee, but to keep the knee from bending. Mr. Batten has found that a twisted skein of natural silk, as obtained from the cocoon, forms an exceedingly strong and light spring to maintain the wings of his model horizontal. A four-skein torse of 23 in. span twisted by a rod or lever in the middle will sustain a boy "weighing 8 st. 2 lb. hanging by his hands 2 ft. 6 in. out along the lever" which is then horizontal. If desired the mere weight of the man could maintain the wings horizontal, but this appears to be more than is required.

In the tentative model (Photos. VI. and VII.) the man's hands grasp two levers controlling the two wings while his feet rest on a firm base board. When his knees are slightly flexed, the wings are horizontal, by pulling against the base board and extending his knees, as in rowing, the wings are depressed, and on bending his knees and relaxing his muscles the wings are raised. The upward movement of the wings will occur from the fall of the body between the wings when the pressure of the air will raise them. If the rhythmic movement be in the same phase and of the same period as the oscillation period of the wings, the wings can be flapped with very little exertion and practically no fatigue. Great attention has been paid to the problem of rising easily from the ground, and also to that of landing.

The book contains valuable suggestions for all who are interested in the problem of flight.

JOURNALS.

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol. XXV. April-June.—Dr. C. P. Symonds contributes a critical review on encephalitis periaxilis diffusa—Schilder's encephalitis. He states that until the publication of papers by Bouman, and Collier and Greenfield in 1924 this disease was unknown except to a few neurologists. It usually occurs in children and young subjects without any obvious cause. The onset lasts a few days and the course is progressive with some remissions to a fatal issue after a duration ranging from a few months to three years. The chief early sign is cerebral blindness, which is followed by mental impairment and increasing spastic paralysis. The condition is usually bilateral but may commence on one side or be confined to one side. The disease may begin in the occipital lobes or in some other part of the brain. In several cases a familial incidence has been noted, which is in favour of an infective cause such as neuro-syphilis, or indicates inherited abiotrophy. Post-mortem examination shows areas of softening in the central white matter of the affected lobes. Histologically, there is general infiltration of the brain with round cells engaged either in the removal of myelin or the formation of glia fibrils. The vessels are surrounded with fat-laden granule cells, phagocytic cells of glial origin, and small round cells of the size and shape of lymphocytes.—In a paper on Hemiplegia associated with Extensive Nævus and Mental Defect Dr. T. Brushfield and Dr. W. Wyatt describe the pathological changes found in the cases of which they had previously related the clinical features. They conclude that the paralytic manifestations may be ascribed to the presence of intracranial nævi and the mental defects only partly to this cause, as they found a definite under-development of the neurones throughout the brain.—Dr. Eric Pritchard reports an Atypical Case of Achondroplasia, illustrated by skiagrams, and comparable to the atypical forms found in animals such as pug dogs.—Dr. Kaj. H. Baagoë, of Copenhagen, records his Investigations on the Pirquet and Wassermann Reactions in Asthmatic Children. From examination of 83 asthmatic children, aged from 2 to 15 years, he found that a positive Pirquet reaction was not more frequent than among ordinary hospital children, thus confirming Wallgreen's view that there is no ætiological connexion between hypersensitiveness to tuberculin and asthma. Examination of the Wassermann reaction in 92 asthmatic children showed that it was invariably negative with the exception of a child suffering from syphilis acquired at the age of 1 year. Baagoë's investigations therefore do not support the view that syphilis plays any part in the development of asthma. —Dr. Robert Hutchison reports a case of Severe Anæmia Treated with Liver in a boy aged 6 years. The case was apparently an example of anæmia gravis, not pernicious anæmia. Immediate and striking improvement, however, followed administration of cooked liver.—Dr. A. Joe records a case of Gangrenous Chicken-pox associated with *B. diphtheriæ* in an infant aged 13 months, which ended fatally.—An Anomalous Case of Deafness Successfully Treated by the Electrophonoïde Method is related by Mr. Macleod Yearsley[1] in a boy aged 10, in whom the deafness was probably due to delayed development. The abstracts from current literature are devoted to diseases of the blood and spleen.

INDIAN JOURNAL OF MEDICAL RESEARCH. Vol. XV. April, 1928.—Dr. A. N. Goyle describes comparative experiments on the transmission of plague by fleas of the genus xenopsylla in which he has demonstrated the superiority of *X. cheopis* over *X. astria* as transmitters of the plague bacillus.—A. C. Craighead and S. Das give an account of a survey of Pusa Estate, the headquarters of the Imperial Department of Agriculture, for sandflies of the species *Phlebotomus argentipes.*—R. N. Chopra, J. C. Gupta, and N. N. Ghosh have studied the Indian varieties of aconite, their chemical composition and biological assay, while the senior workers with various collaborators have completed *similar pharmacological* studies on emetine, ephedrine, and the physical properties of different blood sera.—M. T. Bhaskara has elaborated a technique for making a fairly complete post-mortem examination through an incision in the upper abdomen.—R. McCarrison contributes papers on experimentally produced lymph-adenoid goitre and *on the influence of irrigation* on the nutritive value of rice.—S. S. Sokhey and M. A. Malandkar write upon the pancreatic function in sprue.—W. F. Harvey and K. R. K. Iyengar on *the development, duration, and restoration* of immunity.—W. C. Ross has two papers on cholera.—R. Senior-White, G. Covell, and Bruce Mayne have several contributions in connexion with malaria.—R. Knowles and B. M. Das Gupta record their laboratory studies on Surra, and H. W. Acton describes ainhum, a band scleroderma.

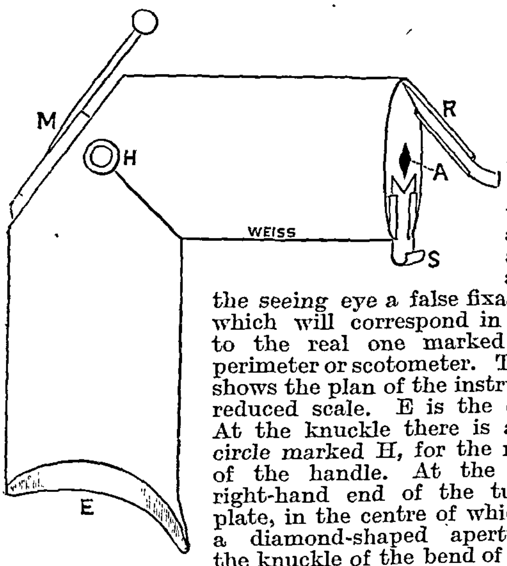
New Inventions.

THE SCOTOGRAPH.



THIS is an instrument designed to facilitate the fields of vision where there is a central scotoma. Field-taking is difficult where the macula of one eye is out of action. The device shown gets over most of these difficulties. A tube is bent at a right angle midway in its length, and the two arms are so arranged as to give the seeing eye a false fixation spot which will correspond in position to the real one marked on the perimeter or scotometer. The figure shows the plan of the instrument in reduced scale. E is the eyepiece. At the knuckle there is a double *circle marked* H, for the reception of the handle. At the extreme right-hand end of the tube is a plate, in the centre of which is cut a diamond-shaped aperture. At the knuckle of the bend of the tube is a large hole covered with a hinged lid M, fitted *inside with a plane mirror.* The patient holds the instrument (the instrument can be fitted with a crank arm to clip on the upright of the perimeter if preferred) before the eye which has fixation power. He sees the patch of light reflected from the mirror lid at the knuckle. The field of vision of the other eye and the scotomata are thereon mapped out. The instrument can be used for either eye.

The Scotograph is made by Messrs. J. Weiss and Son, Ltd., 287, Oxford-street, W.

SAVOY CIGARETTES.

(MESSRS. WIX AND SONS, LTD., 238–248, OLD-STREET, LONDON, E.C. 1.)

ON various occasions cigarettes have been placed on the market, the lip end of which is provided with some kind of filtering arrangement designed to hold back the moisture, pyridine, and solid particles resulting from the combustion of the tobacco. Such filters have had but little success, as they are found in some cases *to impart a flavour to the smoke or they take out too* much and render the smoke tasteless and devoid of character. Generally cigarettes are not smoked to the end, and the stump which is thrown away is about 15–18 mm. in length. This length acts as a filter during the time of smoking, and many of the products of combustion are retained therein. This length of *tobacco is lost to the smoker, while brands of cigarettes* with cardboard mouthpieces cannot be smoked with any pleasure right to the end as the last few draws possess a strong and unpleasant flavour.

The Savoy cigarettes are fitted with a "Styx" filter which, it is claimed, reproduces to a great extent the absorptive characteristics of a similar length of tobacco and shows a greater capacity for retaining the non-volatile particles that are not an asset to the aroma of the tobacco-smoke, and, moreover, are a source of irritation to the throat. No claim, however, is made for an increased retention of nicotine. When examined, the filter plugs are found to consist of three layers of crêped paper, which is not unduly absorptive. *The* paper is wound into *a* spiral, so that no central cavity remains through which a straight stream of smoke would impinge on the tongue. Between the layers of crêpe paper is a layer of cellulose fibre, which constitutes the true absorption medium. The crêpe paper and cellulose fibres are tasteless and odourless, and the end of the plug nearest to the tobacco is treated to render it non-imflammable. A further advantage of the filter plug is that no loose pieces of tobacco can enter the mouth.

We have carefully examined these cigarettes, and having submitted them to physical and chemical tests, we find that the claims described above are justified. The cigarettes, when smoked, are cool and notably less *irritating to the mucous* membrane than the same cigarettes without the "Styx" filter.

THE LANCET.

LONDON: SATURDAY, JULY 14, 1928.

THE RATING OF HOSPITALS.

HE answer to a question in Parliament can be erally correct without being particularly com- ing. Of this nature was Sir KINGSLEY WOOD'S y on the subject of the assessment of voluntary itals. A remarkable diversity of practice has n. At a meeting in Brighton, reported in THE CET last week, it was stated that in Sheffield the itals received special consideration, the assess- t working out at £1 per bed, whereas in Brighton Royal Alexandra Hospital for Sick Children assessed at £14 per bed. The sums demanded other Brighton institutions are alarming. From Royal Sussex County Hospital, which formerly £100 a year, £1600 is now asked; the Children's ital figure has jumped from £16 to £500, and the Hospital from £17 to £100.

e Ministry of Health can state correctly that the er lies not with the central but with the local ority, that the change is not germane to the rnment's new proposals for relief of agriculture industry, and that the hospitals have all their owers of appeal to quarter sessions against over- sment. It is equally true, however, that the tal's difficulties are a national phenomenon and ional concern, and that no hospital is in a hurry end several hundred pounds on lawyers and t witnesses in the uncertain enterprise of nging other experts' figures. If the present g policy involves the bankruptcy of the voluntary tals, the Ministry of Health must take one side e other. If there is no intention of overwhelming ospitals beneath the crushing weight of rating sments, incidents like the new Brighton demands be checked at once. This can be done either e specific declaration of Parliament in favour e exemption, or at any rate the special treatment, spitals; or else it can be done by the adminis- ve action of the local rate-payers who must ce their views upon assessment committees rating authorities. As a practical step, objection be taken to excessive hospital assessments and osals must be made for amendment of the list. e assessment committee can then be persuaded ve the hospitals special consideration, the rating ority and the individual rate-payer will never the hardihood to protest against the mitigation hospital's burden. In this respect the hospitals no different position by reason of the Rating f 1925. It may be admitted that, technically— s to the good sense of the community whose ts they serve—hospitals have in the past been assessed, and it was always possible for objec- be taken to the leniency with which they have reated. But the history of English rating e time of ELIZABETH has been that the local ker, being also the local rate-payer, has d in adjusting the burden to his own shoulders tanding the efforts of Parliament or other o interfere. There is no reason why rate- hould not spare hospitals if they want to. 5 Act has indirectly produced the present ause it has caused a general revaluation of property. Doubtless, in many cases, experts have been called in; the experts, probably paid by scale fees on final figures, have no incentive to maintain the traditional leniency towards hospitals. But the experts and the assessment committees, like the local and central authorities themselves, exist to observe the wishes of the community. There can be little doubt that it is the general wish that the work of the hospitals should not be hampered. This general wish must be made articulate and effective.

The London hospitals are not affected by this special problem as yet. The 1925 Act did not apply to London. Though this year's measures for relief of productive industry from rating burdens will touch the metropolis, the hands of the Minister of Health are, for the moment, too full for him to tackle the big task of reforming the system of London rating. London, however, cannot afford to be indifferent to the difficulties which arise elsewhere, if for no other reason than that her turn will surely come.

◆

SUPPURATION IN THE LOWER RESPIRATORY TRACT.

THORACIC surgery has already many victories to its credit, but in spite of technical progress the treatment of suppuration in the lower respiratory tract may still be very difficult. The same is true of the differential diagnosis, and two critical reviews,[1] by BORDET and SERGENT and by ARCHIBALD, bear witness as much to the need for care and caution as to the efficacy of the methods now available. Radiology has certainly extended our knowledge of the relationship of bronchial to pulmonary suppuration. It is clear that expectorated pus must have either a bronchial or an extra-bronchial origin, and a radiogram taken after the injection of lipiodol affords a clear picture of the condition of the bronchial tree, provided the tubes are patent. Suppuration due to bronchiectasis can thus be distinguished from that due to other causes. But the help to be gained from injection of lipiodol is limited by the fact that its flow may be obstructed, so that it fails to penetrate into a diseased area. An abscess may communicate with a bronchus, but if the fistulous connexion between the two is partially obstructed by granulation tissue, as is usual, the flow of the opaque oil will stop short at the entry. We may therefore divide into two groups those radiograms revealing shadows which suggest the existence of suppuration in lungs or pleura. In the first the injection of lipiodol proves the opacities to be due to bronchiectatic dilatations; these may or may not be complicated by inflammation of surrounding structures, but the primary lesion is in the tubes. The second group comprises the films with shadows which are not penetrated by lipiodol, and these may be due to suppuration within the lung or pleural cavity. Such shadows may be homogeneous or otherwise, the existence of an abscess cavity being suggested by an area in which a dense opacity surrounds a central clearer space. If such a cavity communicates with a bronchus and contains pus, the presence of a fluid level will demonstrate the condition on the film. This appearance may be due to pulmonary abscess, encysted pyo-pneumothorax, or a suppurating cyst. The diagnosis of a large pyo-pneumothorax seldom gives rise to difficulty, but if the collection of fluid is small, and especially if it is near a lung fissure, differentiation between intrapulmonary and extrapulmonary suppuration may be almost impossible. The relationship of the fluid to the parietes of the chest and to the pulmonary shadow may be of help for, as Bernou has pointed out, a characteristic of a localised empyema is that its inner border makes a sharp angle with the parietes. The relationships of a similar collection at the base of the lung may be determined by a radiogram taken when the patient is in the Trendelenburg position, which will reveal the relations of the costo-phrenic sinus. It should not be forgotten that pulmonary abscess is a relatively common condition, whereas a localised empyema is rare.[2] Interlobar empyema is characterised by a triangular shadow, and in the transverse position this slopes in a downward and forward direction. If the pus tracks into a bronchus the appearance of a cavity with a fluid level will be seen, indistinguishable from that of a similar cavity resulting from rupture of a pulmonary abscess. Perhaps the greatest difficulty is encountered when a shadow of more or less uniform opacity is seen, when lipiodol fails to enter the area implicated, and when no evidence of cavity can be detected. This may be due to abscess or to pleural effusion. A cloudy appearance which has been likened to smoke-puffs indicates the probability of an abscess with irregular prolongations in the lung.

---

[1] Diagnostic radiologique des suppurations broncho-pleuro-pulmonaires chroniques: Emile Sergent et François Bordet. Le traitement chirurgical des suppurations pulmonaires: Edward Archibald, M.D. Arch. Med.-Chir. de l'Appar. Resp. 1927, ii., 393-413.

The treatment of chronic pulmonary suppuration is fraught with both difficulty and danger. As H. C. Ballon says, there can be no rule-of-thumb for dealing with an abscess of the lung, a bronchiectasis, or an encysted empyema as though each were a separate entity; for inflammation in the lower respiratory tract is apt to involve bronchi, pulmonary parenchyma, and pleura. The treatment of bronchiectasis depends upon the co-existence of complicating factors. If lipiodol reveals bronchial *dilatation*, and if there is no evidence of accompanying abscess formation, medical treatment by posture, vaccines, and attention to hygiene is indicated. In graver cases, when radiograms show that the process is extending or that ampullary dilatations make drainage by natural methods impossible, further measures must be taken. Ballon has treated 500 cases by direct aspiration, employing the bronchoscope for this purpose. Though cure can seldom be attained by this means, he claims a considerable measure of success in the alleviation of symptoms and improvement in health. He considers that bronchial lavage is dangerous and unnecessary, and though treatment of bronchiectasis by artificial pneumothorax may cause temporary improvement, it is followed by relapse as soon as the lung is allowed to re-expand. Phrenic evulsion seldom, if ever, leads to a satisfactory compression of the dilated tubes. Thoracoplasty holds out small prospect of permanent benefit and the operative mortality is high. To avoid the risks from shock C. A. Hedblom has devised "gradual thoracoplasty," the operation being carried out in from three to seven stages. Even with these precautions he avoids operating when cloudy shadows in the skiagram suggest that the bronchiectasis is complicated by pulmonary suppuration. Treatment which may demand seven operations, and is only applicable to uncomplicated forms of the disease, seems to have little to commend it. Lobectomy, following ligature of the bronchi and vessels of the diseased lobe, is more dangerous than thoracoplasty and no better in its results. A more hopeful method is that of E. A. Graham, who practises pneumectomy by cauterisation. After resection of portions of three or four ribs and the formation of adhesions to protect the healthy pleura, the diseased tissues are removed by the thermo-cautery. Several applications of the cautery may be necessary to remove all the diseased tissues, and a mortality of at least 20 per cent. may be expected after this comparatively safe procedure—a striking commentary on the dangers attending surgical interference in bronchiectasis.

The classical operation for chronic pulmonary abscess is pneumotomy and drainage, following rib resection and the formation of adhesions to protect the pleural cavity. Immediate improvement has been the rule, but closure of the wound has almost inevitably been followed by recurrence of symptoms and further pus formation. The cause of these disappointing results has been explained by the use of lipiodol. Bronchiectasis is a frequent complicating factor in pulmonary abscess, and it is useless to drain the abscess if neighbouring bronchi are dilated and harbouring pus. E. Archibald has abandoned simple lobectomy in favour of Graham's method of cautery pneumectomy. A more extensive rib resection than that practised in lobectomy is carried out and adhesions are provoked by packing with gauze. At a second operation the abscess is opened by means of the thermo-cautery and the cavity is packed. At a later date lipiodol is injected into the cavity and a radiogram is taken to ascertain if there are any residual bronchiectatic lesions or secondary abscesses. Any further destruction of diseased tissues is carried out by means of the electro-coagulating needle. Thus, while simple pneumotomy may suffice for the treatment of acute abscess or for a simple circumscribed abscess near the surface of the lung, pneumectomy by cautery is the operation of choice for the complicated or deep-seated forms. Lobectomy may be a more *radical operation* but, as Archibald remarks, a living man with a fistula is worth several dead men cured by lobectomy. The operative mortality for the latter operation is given as 57 per cent.

◆

DEAFNESS AND INDUSTRIAL DISABILITY.

Total deafness, or anything approaching total deafness, is a far more terrible affliction than is easily realised by the general public, but unlike blindness, it does not make an immediate and universal appeal to compassion. It is a familiar fact that a blind man instantly excites our pity, while a deaf one is somewhat annoying. The consequence is that, of all forms of charitable effort, the agencies which have long striven to help the deaf in this country are about the worst supported. The skilled assistance which can be given to the totally deaf will usually turn them rapidly into people who can be valued and self-supporting members of the community; but this assistance is by no means always forthcoming, and the standard of our care for the deaf is lower than for almost any other comparable class of afflicted people. Those who are deaf from birth, or become severely deaf at an early age, are also necessarily dumb. Of these it is reckoned that there are about 40,000 in Great Britain, but there are no satisfactory statistics to show the number—certainly far greater—of those who become so deaf later in life as seriously to interfere with their employment. For deaf children, up to the age of 16, local education authorities, and the Education Department, have been doing for many years extraordinarily good work. These children, however, when they leave the special schools, together with all who have become deaf in later life, are at a great disadvantage in finding employment. It is true that many agencies, mostly missionary societies, exist for the purpose of giving them help, but these have great difficulty in obtaining funds, and they are unable to assist more, at most, than half the deaf people who are in need of their services. Of those who have become deaf after childhood, men whose deafness was brought about by the war are dealt with by the Ministry of Pensions, and on the whole quite adequately; but for the far larger number who have become disabled in civil life there is virtually no help at all.

---

[2] See THE LANCET, 1923, i., 1336.

All this was admirably stated a few weeks ago by Lord CHARNWOOD, who performed a notable service to deaf people by raising the question in the House of Lords, when he asked the Government to institute an inquiry. It is much to be regretted that Viscount GAGE, for the Government, was unable to accede even to this modest request, chiefly on the ground that, if machinery like that set up to deal with the blind is applied to all congenital affections, the Ministry will have a great financial load placed upon it. It is perhaps some consolation that this reply appeared to be unsatisfactory to his hearers; indeed, Viscount HALDANE raised the criticism that it had been prepared before the debate came on, and before anybody could know what was going to be said. It is a waste of money to teach deaf and dumb children, unless there is adequate machinery to assist in their employment when taught, and it is probable that Government assistance to the existing societies would prevent much of this waste at little cost. In any case, the inquiry asked for would cost little or nothing, and would do much good by stimulating public interest where it is sorely needed.

◆

PRESENTATION TO SIR GEORGE MAKINS.

ON Wednesday, June 20th, in the Governors' Hall at St. Thomas's Hospital, Sir George Makins was presented with his portrait, the gift of his friends, pupils, and colleagues. The painting is by Mr. James S. Sleator and is a sound piece of work. The proceedings, which were quite informal, were opened by Sir Arthur Stanley, treasurer of the hospital, with a few warmly appreciative words on behalf of the governors. He was followed by Sir Percy Sargent, Sir Cuthbert Wallace, and Dr. H. G. Turney, who as friends and colleagues of different periods dwelt in turn on the length and value of Sir George's services to the medical school and hospital, and on the affectionate regard in which he was held by all with whom he was associated. Special reference was made to Lady Makins who had taken so large a share in establishing and maintaining these kindly relationships. Sir George, in reply, expressed his profound appreciation of the honour done to him.

All the medical profession will unite in appreciation of the action taken by St. Thomas's Hospital, for Sir George Makins, though a great St. Thomas's man, is a representative of the best scientific and professional development which medicine throughout our country—and the world—has seen during the past half century. His work commenced when the verities of the Listerian teachings had been established, and he has been a leader in all the advances which followed—advances which, while they were most openly reflected at first in the enlarged scope of operative surgery, have since revolutionised the whole of medical work. How clearly throughout this onward march Sir George Makins has been recognised as a protagonist is shown by the high responsibilities which have at different times been laid upon him by his country and by his colleagues as man of science, practising surgeon, and wise administrator.

Annotations.

"*Ne quid nimis.*"

THE BRITISH MEDICAL ASSOCIATION'S ANNUAL MEETING.

FORTY-THREE years have elapsed since the British Medical Association last visited Cardiff, and the annual meeting which opens there in ten days' time will be the ninety-sixth in its history. Sir Ewan Maclean, the incoming President, will give his address on the evening of Tuesday, July 24th, and the scientific sections will meet, as usual, on the three days following. Their programme from year to year shows the gradual enlargement of the scope of medicine, and the task of selecting subjects grows ever more embarrassing. Nevertheless, the organisers have once again succeeded in arranging meetings that reflect many of the main tendencies of medicine—and especially clinical medicine—at the present time. While the physicians are to discuss diseases of the coronary arteries, the prevention and treatment of diphtheria, and the problem of acute nephritis, the Section of Surgery will consider such subjects as pancreatitis, the diagnosis and treatment of spinal cord tumours, the treatment of gangrene, the diagnosis of ureteric calculi, and (with the Section of Radiology) the fallacies of radiography in abdominal diagnosis. The vexed questions of unsuccessful forceps cases and sterility will again be raised at the Obstetrical Section, which will also hear papers on other topics, whilst the Section of Mental Diseases and Neurology will devote its attention to autotoxæmia in relation to the causation of psychoses, the differential diagnosis and treatment of cerebral states following head injuries, and the early treatment of psychoses and psychoneuroses. Of special interest at the present time will be the discussion at the Pathological Section on encephalitis occurring in the course of virus disease and the exanthemata, and another occasion of importance in connexion with vaccination will be the session devoted by the Section of Preventive Medicine to the value of present methods of controlling infectious diseases. Without reproducing the entire programme it is impossible to give a fair idea of the topics chosen for discussion, ranging as they do from the medical treatment of gastric disease to the decline of the birth-rate. Enough has been said, however, to show their catholicity and their appropriateness. The meetings will be held in the mornings, and will be interspersed with dinners, receptions, excursions, and other social events. As usual, the meeting of representatives of the Association will be held before the scientific sessions, and it will open on the morning of Friday, July 20th.

LITTLE FLEAS AND LESSER FLEAS.

THE aggregation of man into concentrated communities has produced most of the problems with which modern hygiene has been mainly concerned. In nature hosts and parasites have generally come to some sort of stable balance with "live and let live" as its motto. Of this we should know more if we understood the parasitology of wild animals better: trypanosomes in game in Africa and Gaertner's bacillus in rats at home are familiar examples. Similarly, when vegetable crops are grown over wide areas in more or less pure culture, special troubles with parasites generally arise. This is particularly apt to happen when the plant itself has been moved from its natural home; coffee, for example, and rubber and bananas and oranges are now grown all over the world where climatic conditions are appropriate. Along with this transportation of hosts there has been a dispersion of parasites, and out of the troubles that have come from upsetting the balance natural to any country has arisen an extraordinarily interesting chapter of biology. The parasites of a plant are, it seems, normally controlled and kept within bounds by a second series of parasites, and these again sometimes by a third. In the moth *Pyrausta nubilalis*, for instance, something of a pest to corn in Southern Europe and a serious injury in the United States since its introduction in 1910, 18 parasites (mostly insects) have been found to make their living on the larva, one on the egg, and two on the chrysalis.

If a parasite gains access to a new country without its own parasites it is obviously in a very advantageous position, of which it may make full and foul use, and similarly the multiplication of a host on an unprecedented scale may give parasites a chance to increase beyond the controlling powers of the secondary parasites. The plain remedy is to encourage or introduce the parasites of the parasite, and in a number of instances this plan has been put into operation with signal success. An Australian ladybird, for instance, has proved a perfect remedy for the cushion scale of oranges and lemons in California, Portugal, South Africa, Egypt, and elsewhere. A chalcid wasp from South Africa similarly controls the black scale insect in California, and the Italian silk industry has been saved from ruin by importing a parasite of the scale insect which destroys the mulberry trees. Plants which grow too profusely have in the same way been brought within bounds by importing insects which feed on the seeds. The problems involved are very complex, and Dr. W. R. Thompson, who works at the laboratory maintained at Hyères for the purpose by the United States Government, contributes a thoughtful survey of the ramifications of inter-relationships which are involved to the last number of *Parasitology* (1928, vol. xx., p. 90).

The general principles discussed are applicable to many problems of human hygiene, and the details have, of course, a very intimate bearing on the control of the insects which carry disease and of human parasitic worms. Some years ago an ingenious suggestion was made by Dr. B. S. Elgood and Major T. Cherry [1] that bilharziasis in Egypt might be controlled by encouraging the native population in the villages to keep ducks. The suggestion arose from the observation that the snail, which is the intermediate host of the bilharzia, is absent from those ponds and lakes to which ducks have free access, whereas they are abundant elsewhere. It would be interesting to learn whether this scheme was ever tried out. d'Herelle would have us believe that bacteria may be curbed by encouraging his *Protobius bacteriophagus*: it may be so. But it is certain that African sleeping sickness will ultimately be controlled only by finding out how the tsetse-fly lives and moves and has its being; by discovering its parasites and other difficulties and increasing them; and by ascertaining its favourite food and the conditions of life which it likes, and by destroying them.

THE INFLUENCE OF DIET ON HÆMOGLOBIN REGENERATION.

So sensational were the results of the application of the liver treatment to primary anæmia that a more or less universal disappointment was experienced when its effects in secondary anæmias were pronounced to be slight. In fact, the indefinite results in these cases as compared with the remarkable improvement induced in cases of primary anæmia led many observers rather hastily to conclude that liver is without effect in any type of anæmia other than the primary or Addisonian. Further experience has caused most of those who have investigated the matter to modify their views, and clinical experience is beginning to show that liver is not without beneficial effects even in the secondary anæmias. Prof. G. H. Whipple has been able to show that in experimental animals liver has indeed a powerful effect in inducing hæmoglobin regeneration in secondary anæmia. This effect is not confined to liver but is shared in lesser degree by many other foodstuffs. In the June issue of the *American Journal of the Medical Sciences* Prof. Whipple summarises the results of tests on various articles of diet carried out under his direction in the Department of Pathology of Rochester University. The experiments were made on dogs brought to a standard degree of anæmia by repeated bleedings, and they appear to have been subjected to rigid control. Of all the articles of diet tried beef liver produced the most rapid regeneration of hæmoglobin; second to this came beef kidney, and then chicken gizzard, the index of which works out at 85, compared with 100 for beef liver. Chicken liver had a powerful effect, but fish liver appeared incapable of producing the slightest regeneration of hæmoglobin. Prof. Whipple found various vegetable substances to be effective, though none of them to the same extent as mammalian tissue. Thus apricots, apples, raisins, and prunes all showed considerable power; raspberries were as inactive as fish liver. "The leafy vegetables," says Prof. Whipple, "have a reputation much better than they deserve. . . . We can furnish no evidence of unusual blood regeneration following liberal diets of various greens. Beet greens, spinach, asparagus, and lettuce all show values of between 5 and 20 g. hæmoglobin production per two week period above the control level," as opposed to 100 for beef liver. Iron in the form of ferric citrate was found to bring about a material increase in hæmoglobin formation but the response was improved by the addition of liver; it was possible to demonstrate a liver reaction superimposed upon an iron reaction. Prof. Whipple appears to have come to the conclusion that the favourable results produced in secondary anæmia by the exhibition of suitable dietary factors, of which liver is only one, is due not to the activity of any hormonic substance but simply to the supply of the building-stones in the form of suitable amino-acids necessary for the elaboration of hæmoglobin. That the hæmoglobin of the muscle may be called upon to a limited extent to supply deficiencies of the blood hæmoglobin is a further observation arising out of this work. It has been shown, however, by biological tests that the hæmoglobin molecules derived from different tissues are not identical. It is probable that muscle hæmoglobin must be completely broken down before it can be utilised for building up blood hæmoglobin. These experiments are likely to help in the elucidation of the biochemistry of the blood as well as in therapeutics, and we trust that they will be continued and extended.

ULCERATIVE COLITIS.

THE bacteriology of chronic ulcerative colitis still gives rise to lively controversy. In 1924 J. A. Bargen reported from the Mayo Clinic that he had found a Gram-positive diplococcus in 90 per cent. of cases, and vaccines prepared from the organisms have been used at the Clinic with apparent success in treatment of the condition. But although Bargen found that freshly isolated cultures of the diplococcus produced diarrhœa and ulceration of the colon in rabbits and dogs, other workers have not wholly accepted his organism as causal; M. Paulson, of Baltimore, for instance, has reproduced the disease with various strains of streptococci which appeared in diplococcal form when freshly isolated. E. MacNaughton,[1] of Montreal, now brings forward support for Bargen's view by reporting the association of a diplococcus with five cases of ulcerative colitis, one of these cases being especially interesting because the appendix was removed after ileostomy, and in its mucosa there was an unruptured abscess from which a pure growth of Gram-positive diplococci was obtained. The characters of Bargen's diplococcus are identical with those of the "enterococcus" which French bacteriologists have long regarded as pathogenic, causing enteritis in infants and adults, and some forms of meningitis, and appearing as a secondary invader in cases of tuberculosis and paratyphoid fever. This organism was prevalent in the "fæcal infection" of wounds sustained on the Flanders front and on Gallipoli in 1915. It seemed to be of low virulence, but gave rise to a chronic indolent inflammation on invading the damaged muscles. Accidental infection of operating surgeons and laboratory workers occurred several times; the cases were slow in evolution but resistant to treatment. After the inoculation of large doses of killed organisms as vaccines in healthy persons no immunity reactions could be demonstrated. This diplococcus may need to be watched for as a secondary invader, but the primary ætiological factor in chronic ulcerative colitis is, we feel, as yet undiscovered.

THE COW AND UNDULANT FEVER.

IN the Court of Public Health the cow frequently stands in the dock on the charge of conveying disease to man. On some counts she eventually secures an acquittal—for instance, as a sufferer from scarlet fever—while on others, and particularly tuberculosis, a fair but protracted trial has resulted in a verdict of guilty with extenuation as regards the amount of disease transmitted. Fresh diseases, however, continue to be laid to her charge; for example, the last few years have shown that food poisoning of the salmonella type may sometimes be traceable to bovine infection, members of this group of bacilli being excreted in the milk.

The most recent indictment is that the cow is a source of undulant fever in man, and this involves consideration of an interesting field of veterinary-medical pathology. Malta fever, or undulant fever as it is now more generally called, was shown by Bruce in 1887 to be due to an organism called by him *Micrococcus melitensis*. Its relationship to infected goats and goat's milk was subsequently established. About 1897 Bang in Denmark showed that a bacillus named by him *Bacillus abortus* was the causal organism of contagious abortion in cattle. For many years no relationship between the two organisms was even suspected, and it was only after a further decade that comparison of the two types showed their extremely close agreement. This comparison was made by Miss A. C. Evans, of Washington, who further showed that infection with the organism of Malta fever tends to produce abortion in goats, whilst in later experiments she found that inoculation of cows with strains from human cases of Malta fever results in abortion. These findings have been confirmed and amplified by a number of other observers. In a further report in 1923, after a study of many types, she finds that strains of the *melitensis-abortus* group isolated from five species of animals fall into two distinct serological types which are closely related. One type, which may be called the *abortus* type, is characteristically bovine and porcine: the other, which may be called the *melitensis* type, is characteristically human and caprine. The types are not, however, restricted to special host species. The general opinion which is gaining ground is that *melitensis* and *abortus* are not distinct bacteriological species, but merely distinct serological types of the same species. *B. abortus* is not uncommon in England, and Wilson and Nutt in 1926 have recorded its presence in cow's milk in this country. In a recent paper Dr. P. Manson-Bahr[1] gives a summary of four sporadic cases of undulant fever in this country, most of which were not explicable on the grounds of infection with goat's milk. In addition he gives particulars of two further cases of his own, both of which were probably due to infection through cow's milk. He suggests that other cases might be found by closer observation of districts where bovine abortion is endemic.

At the last meeting of the permanent committee of the Office International d'Hygiène Publique it was reported that work in Sweden and Denmark had confirmed the view that *B. abortus* is the causative agent of undulant fever, and it was stated that this infection, "propagated by milk or cattle, is shown to be more frequent in the latter country than typhoid and paratyphoid fever." A good many obscurities remain, however, which can only be cleared up by further investigations. For example, a considerable percentage of sera from persons not suffering from disease give a serological reaction with *B. abortus* antigen. The significance of this has not been established. Contagious abortion in cows is common in certain areas while human infections are probably rare. This may be because in infected cows *B. abortus* is only present in quite small numbers in the milk, or it may be a question of low virulence to man. The general position may be summed up by saying that the evidence goes to show that there is a risk of undulant fever being transmitted through drinking raw infected cow's milk, but as yet insufficient data are available to measure the extent of that risk or even to show if it is more than remote.

THE NEW ZEALAND HOSPITAL SYSTEM.

BY way of an appendix to its annual report the New Zealand Department of Health has issued an elaborate survey of the hospital system of the Dominion, called forth mainly by the recent considerable increase in expenditure. The New Zealand hospitals are maintained partly out of the rates, partly by Government subsidies, and, to a much smaller extent, by voluntary contributions, which relieve the rates but not the taxes. Notwithstanding that help, even in comparatively slender degree, is derived from private sources, the document adopts a rather scornful attitude towards the voluntary system, which it describes as based upon "sentimental appeals." The Health Department is satisfied that the hospital arrangements of the Dominions are "unique," and that no real improvement in the financial method of maintenance has yet been proposed. In one respect, however, something less than perfection has been attained. "The only fault in the hospital system of New Zealand arises out of the number of hospital districts," and it is recognised that it is desirable to have thoroughly equipped modern hospitals serving larger districts, although the cost of even one such institution in each of the 47 districts would be prohibitive. Therefore, not only must no new districts be created, but existing ones must be amalgamated, a process which is greatly hampered by "selfish and parochial" opposition. Even under the system which is thus admitted to be imperfect, the cost of the hospitals has gone up by 150 per cent. in the last ten years, for much the same reasons that have operated in England. There has been a notable increase in the number of beds, which have grown from 5929 in 1923 to 7060 in 1927. The explanation of this expansion is that in New Zealand, as elsewhere, a greater proportion of the population is using the hospitals. This tendency of all classes to resort to the hospitals is held to show that there is no real need for the provision of private wards, though the Department of Health would be willing to see at least one hospital try the experiment. In one respect the New Zealand hospitals differ materially from those in the Motherland. In the Dominion the out-patients are fewer, in proportion, than the in-patients; there is, however, a tendency to develop the out-patient departments of the general hospitals. Upon the difficult question of the payment of medical staffs the Survey is emphatic. The Director-General of the Department is definitely of opinion that "the time has come for the abolition of the honorary staff," and he lays it down that "the honorary system is only suitable for hospitals treating only pauper patients." Neither the New Zealand branch of the British Medical Association nor the Dominion's Hospital Boards Association has expressed quite so sweeping a view, and so far no action has been taken.

THE TREATMENT OF ILEUS BY SPLANCHNIC ANÆSTHESIA.

ACUTE ileus, whether due to some mechanical obstruction, to atony, or to spasticity of the intestinal musculature, is one of the complications most dreaded by the surgeon. Numerous methods of treatment have been tried, both operative and therapeutic, and have recently been reviewed in our columns[1] by Mr. A. H. Southam. In a certain percentage of cases enterostomy is successful, but sometimes neither fæcal matter nor gas is discharged through the enterostomy opening and no relief of symptoms ensues. The suggestion that ileus might be satisfactorily treated by blocking the splanchnic nerves has recently been made by A. Ochsner, L. M. Gage, and R. A. Cutting,[2] as a result of a series of carefully conducted experiments on animals. The suggestion has a sound theoretical basis. Bayliss and Starling showed that physiological ileus could be abolished by resection of the splanchnics, and P. Rosenstein and H. Kohler found that procaine hydrochloride solution introduced into the splanchnic area of rabbits produced peristalsis. In those cases of paralytic ileus which are due to the inhibition of intestinal mobility from impulses passing by way of the sympathetics, the blocking of the reflex arc should abolish the inhibition. This mechanism accounts for the good results obtained by continental surgeons from the use of spinal anæsthesia. The procedure is not, of course, applicable to cases of mechanical obstruction where, in the early stages, there is no interference with the contractibility of the intestinal musculature. In any case spinal anæsthesia is not without its dangers. Splanchnic anæsthesia appears to be a safer procedure. Ochsner and his co-workers adopted the method devised by M. Kappis, using a 1 per cent. solution of procaine hydrochloride injected into each side at the lower border of the twelfth rib. Their experiments showed that splanchnic anæsthesia will produce peristalsis in physiological, chemical, and mechanical ileus in dogs, and there seems no reason why it should not be applied clinically to cases of paralytic ileus following operation, or to those which arose from mechanical obstruction, but do not clear up when the obstruction is relieved. Even when enterostomy has been performed, splanchnic anæsthesia might be valuable when toxæmia persists owing to the continued paralysis of the musculature and the inability of the intestine to expel its contents. The advantage of the Kappis method is that the abdomen need not be opened, the splanchnic area being approached through the retroperitoneal space and not through the peritoneal cavity. Reports as to the results of clinical trial of this method will be awaited with interest.

THE TAXING OF KNOWLEDGE.

Captain Ian Fraser's attempt to introduce into the Finance Bill a clause exempting scientific films from import duty met with the blankest *non possumus* from the Financial Secretary to the Treasury and only a faint hope was held out by the Chancellor of the Exchequer. The answer of officialism is that exemption would be "difficult and indeed almost impossible to administer." For ourselves we entirely decline to believe that it is beyond the power of expert draftsmen to frame, or of sensible civil servants to operate, a clause exempting films which are wholly educational in character. Exactly the same discrimination is applied elsewhere in connexion with the entertainments duty, and there is not the slightest reason why, as Captain Fraser suggested, the customs officials should not be satisfied with the certificate of the Royal Society, the British Medical Association, the Royal Astronomical Society, or other accredited body of the same sort. The Privy Council Committee for Scientific and Industrial Research seems a suitable organisation for the purpose. Nor need the proposed exemption cause a multiplication of officials; the country is evidently well equipped with personnel. Prof. H. H. Turner recounted, in a letter published in the *Times* of July 3rd, the experiences of a distinguished American astronomer who came over to lecture to the Royal Astronomical Society on the atmospheres of the planets and who brought with him two cinematograph films of the successive phases of Jupiter. He produced the films from his luggage at Victoria Station, explaining their nature and purpose. The films were impounded. Help was sought, says Prof. Turner, from the Royal Observatory, and the customs officer was assured of the integrity of the lecturer and his scientific purpose. Next morning Mr. A (the officer thus assured) introduced the lecturer to Mr. B in an adjoining office, who gave him papers to be carried to Mr. C elsewhere, who arranged for a meeting with Mr. D in the afternoon, as the result of which an order was made for removal of the films to the Bonded Film Stores in Endell-street. There the lecturer explained the situation to Mr. E, who introduced him to Mr. F, who sent him back to Mr. C, who referred him to Mr. G, who gave him an order on Mr. F for delivery of the films at Endell-street, on payment of duty. This occupied two days; part of the third day was devoted to official arrangements for return of one of the films (a reserve film) to America; the total expenses were about £4, including a fine of 2s. 6d. for the alleged offence of carrying "merchandise" in a trunk. What the distinguished American astronomer may have thought at this British adaptation of Ellis Island procedure—for fear a little scientific knowledge should creep into this country untaxed—is not recorded. What the opinion of the English public will be we would venture to guess. The use of the cinematograph in revealing to the medical profession the latest results of foreign research needs no emphasis. The Exchequer and the customs officials are the country's servants and not its masters. They must find some means of doing even what is "difficult and indeed almost impossible."

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE eighteenth annual meeting of the Ophthalmological Congress, held last week at Oxford, was attended by about a hundred members. On Thursday Dr. Leonard Hill opened a symposium on ultraviolet rays, dealing principally with the physics of the subject. In disease, he said, the beneficial action of the rays depended upon appropriate dosage, too large doses being liable to do harm. Healthy subjects, on the other hand, were subject to comparatively little risk. How the beneficial effect is produced remains to a great extent a mystery. It has, however, been definitely proved that one effect is to increase the bactericidal action of the blood and further, that minute amounts of ergosterol are activated by the rays to produce vitamin D. Dr. N. S. Lucas gave his experience at the Zoo and at the Lister Institute where the rays have been proved to be curative for rickets in monkeys. As to their application to ophthalmic therapy not much was said. Friday's programme included a paper by Mr. Burden Cooper on the spectroscopy of the crystalline lens. The ash shows traces of various metals, and it may be significant that there is considerably more calcium in the ash of cataractous lenses than in that of normal ones. A discussion on sympathetic ophthalmia was opened by Mr. Harrison Butler. Recent advances are in the direction of diagnosing the disease in the exciting eye before the sympathising eye has become affected, the main points of interest being how far the differential blood count is a valuable diagnostic sign and how far the evidence of the slit-lamp is of practical service in diagnosis. Mr. Harrison Butler had not found the former of much service and relied chiefly on the latter. Mr. S. H. Browning and Mr. M. Hepburn joined in the discussion. The latter recalled his paper on the subject read to this congress in 1926 and stated that in possible cases of sympathetic disease he always had a blood count taken, and if it were positive began the injection of arsenical compounds at once. The discussion was followed by the delivery of the Doyne Memorial Lecture by Prof. Arthur Thomson, whose subject was "Observations on the Eyes of Birds" and his main thesis a theory of the function of the pecten, a structure which has been a mystery to anatomists for 250 years. The theory is that the pecten, being a deeply pigmented body and being lined with a thin hyaloid membrane, acts as a dark mirror, reflecting objects from a direction other than that of the bird's flight on to the retina, and avoiding dazzle. The suggestion was made that it acts as a sort of periscope, causing the bird in its flight to be aware of any bird of prey hovering above him in the sky. The demonstrations included an ingenious apparatus for educating the amblyopic eye of young children by Mr. E. Maddox, a selection of Hamblin's fundus drawings demonstrated by Mr. Rayner Batten, different applications of the duochrome principle to refraction and other ends. Lighter items of the programme included a garden party, at which Prof. and Mrs. R. A. Peters, of Trinity College, were hosts, the annual dinner at which Sir Farquhar Buzzard, the new Regius Professor of Medicine, was the chief guest, an excursion to the Morris Motor Works, and the inevitable photograph.

THE ALCOHOL PROBLEM.

THE effect on the sobriety of the nation of the restrictions on the production and sale of alcoholic liquors during the war was discussed by Dr. H. M. Vernon in an address delivered to the Society for the Study of Inebriety on July 10th. According to him the most important feature of the control was the regulation of the hours of sale. When no liquor could be obtained before mid-day or between 2.30 to 6 P.M., it was, for the most part, taken only with food and was thereby rendered much less harmful. The arguments in favour of the limitation of the hours during which public-houses are open and of the taxation of wines and spirits, according to their concentration, are well set out in Dr. Vernon's recent book,[1] which we commend to anyone who wants to know what has been achieved and to reflect how further progress may be made. It is a plain, easy, straightforward account of the physiological effects of alcohol and of the various systems of regulation and prohibition which different countries have tried, with their results, including the improved public-house. Dr. Vernon is an experimentalist and with the aid of numerous tables and diagrams he appeals continually to experience: the efficacy of the operations of the Liquor Control Board is measured in the same spirit as that which moves him to determine how much whisky of what strength he must drink before he can no longer work a typewriter. He probably has some general prejudices on the subject, but he keeps them out of sight as much as any man may, and it is only because he tells us so that we know he is one of those really moderate drinkers who are the despair of the ardent teetotaler. Of complete prohibition as a practical proposition for to-day he thinks poorly, and he attaches much more importance to control based on the physiological facts, ascertained by experiment, that alcohol is less intoxicating if it is taken when the stomach contains food and if it is well diluted. He advocates, therefore, a stringent pursuit of the plan at present prevailing in this country of making alcohol easily available only round about meal times and, by differential taxation, making concentrated alcohol more expensive than dilute. He would indeed exaggerate the difference by cheapening beer which contains as little as 3 per cent. of alcohol on which it is almost impossible for anyone of a normal capacity to get drunk.

THE PROGRESS OF DERMATOLOGY.

THE May number of *American Medicine* is consecrated to dermatology, and among a heterogeneous collection of original papers is one by Dr. E. L. McEwen, of Chicago, which admirably assesses the progress of the last ten years and helps to clarify the subject for practitioners, to whom the thesis is addressed. "What does the general practitioner see in dermatology?" asks Dr. McEwen. "He sees a jungle, to him more or less impenetrable, with trails that are poorly blazed, devious, full of pitfalls, and leading more often to denser thickets than to open spaces." The metaphor could hardly be better chosen, for there is no branch of medicine in which progress has been more sudden. Before the discovery of the spirochæte there was an increasing tendency towards portentous nomenclature, serving chiefly as a ragged veil to ignorance. With the solution of many ætiological problems, among which may be mentioned the tuberculides and eczematoid ringworm, and the recognition of the importance of focal sepsis and allergy in cutaneous manifestations, the veil is lifting, and if progress is maintained at the same rate it is reasonable to hope that before long we may be in a position to throw light on psoriasis, pemphigus and mycosis fungoides. The elucidation of the problem of eczema is well under way, and Dr. McEwen accepts the differentiation of dermatitis as opposed to eczema by relegating to the former all cases that are clearly of external causation, or "nearly so," classing in the eczematous those cases whose cause is suspected of being purely internal. He draws attention to the reduced likelihood of any given eruption being syphilis, which a generation ago had a statistical frequency of over 11 per cent., and was second only to eczema among dermatological diagnoses. In this branch of medicine the introduction of various chemotherapeutic remedies, such as salvarsan and the X rays, radium and ultra-violet rays, have greatly strengthened our hands of late years, and the journal under review bears witness to a new and hopeful outlook.

DEATH OF DR. POTTEVIN.

MEDICINE in its broadest sense has lost a good friend by the death on July 6th of Dr. Henri Pottevin, Director of the Office International d'Hygiène Publique. He had a cerebral hæmorrhage shortly after the May session of the Permanent Committee and a second last week which proved rapidly fatal. Effective international health work has many difficulties, but as far as the Office International was concerned these were surmounted by the ardent, quick-brained Frenchman of the Midi who had a positive genius for consolidating and interpreting the contributions and opinions of men from other countries and of combining them, wherever it could be done, into logical statements and agreements. Henri Pottevin was in his sixty-third year, a doctor of medicine and science, a collaborator of Pasteur in his early days, and always in touch with the Pasteur Institute. He was director of the health office of the town and port of Havre for some years, and was appointed general secretary of the Office International from the date of its foundation in 1907, succeeding Cazotte as Director in 1926. He had many other activities, notably as a Professor in the Conservatoire des Arts et Métiers in Paris, and he had an active political life which led to his being appointed a Senator of his native department, Tarn et Garonne. He left the Senate only last year. From the British point of view he will perhaps best be remembered in connexion with the various official conferences at which the successive international sanitary conventions relating to infectious disease and quarantine were concluded. In that of 1912 he was rapporteur for all technical questions, and in the recent conference of 1926 he was rapporteur général and, in point of fact, the management and satisfactory conclusion of that international instrument could never have been achieved without him. Much had been hoped from his appointment, immediately after that conference, as director of the Office International, especially since he had seen this organisation grow from being representative of a small number of countries to one to which practically every Government now officially adheres, and whose Permanent Committee accepts the additional responsibility of advising the Health Organisation of the League of Nations. He will be remembered gratefully by those who, towards the end of the late war, used to attend the Inter-Allied Sanitary conferences for comparison of data regarding the prevention of disease in the different allied forces.

[1] The Alcohol Problem. By H. M. Vernon. London: Baillière, Tindall and Cox. 1928. Pp. 252. 9s.

THE International Cancer Conference meets in London from July 16th to 20th. Delegates from nearly every important medical school and university in the world will attend its scientific meetings, which are to be held at the houses of the Royal Society of Medicine and of the College of Nursing. Owing to the limited space only a small number of tickets of admission are available, for which application should be made to the Secretary of the Conference, at the Royal Society of Medicine, 1, Wimpole-street, London, W. 1.

Sir Robert Philip, Professor of Tuberculosis in the University of Edinburgh and President of the British Medical Association, has been awarded the Trudeau Medal of the American National Tuberculosis Association. This medal is given annually to the person who has made the most meritorious contribution to the knowledge of the cause, prevention, and treatment of tuberculosis.

ROYAL SANITARY INSTITUTE.

ANNUAL CONGRESS.

THE thirty-ninth congress of the Royal Sanitary Institute will be held at Plymouth in the Guildhall and Council Chamber by invitation of the municipal authorities during the week ending July 21st. Delegates have been appointed by the principal Government departments dealing with health and sanitation, while all parts of Great Britain will be represented by sanitary authorities, societies, and universities. Representatives from our dependencies, from the United States, and the principal countries of Europe will also be present. The reception room will be opened in the St. Andrew's Abbey Hall at noon on Saturday, July 14th, and on the following day, Sunday, there will be a service at St. Andrew's Church in the morning and one at the George-street Baptist Chapel in the evening. Following the reception of members and delegates by the Mayor, there will be a public luncheon in the Royal Hotel, at 1 P.M. on Monday, July 16th; the opening of the Health Exhibit will take place in the Drill Hall in the afternoon, and the inaugural address will be given by Viscount Astor, the President of the Congress, in the Guildhall, at 5 P.M. The work of the sections will be spread over the following. Tuesday, Wednesday, Thursday, and Friday, the Presidents being: Preventive Medicine, Dr. L. Rajchman, Medical Director and Secretary of Health Committee of the League of Nations; Maternity and Child Welfare, including School Hygiene, the Viscountess Astor, M.P.; Personal and Domestic Hygiene, the Mayoress of Plymouth; Hygiene of Food, the Prime Warden of the Worshipful Company of Fishmongers; Hygiene in Industry, the Rt. Hon. Ramsay MacDonald, M.P. Other sections include veterinary hygiene, engineering, and architecture, and there will be conferences by representatives of port sanitary authorities and National Health Insurance societies as well as of medical officers of health and health visitors. Among the large number of important subjects to be discussed are: tuberculosis, scarlet fever and measles, puerperal fever, fœtal mortality and injuries, the rheumatic child, the influence of environment on the mental health of the child, factory conditions, cremation, housing, and humane methods of cattle slaughter. A popular lecture will be delivered on the evening of Friday by Prof. W. E. Dixon, of the Pharmacological Laboratories, Cambridge, the subject being Poisoning in Daily Life. Both on Friday and on Saturday there will be excursions to various places of interest in connexion with health and sanitation. The offices of the Institute are at 90, Buckingham Palace-road, London, S.W., and the local offices are at the Town Hall, Stonehouse, Plymouth.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXXIV.—TREATMENT OF MIGRAINE.

MIGRAINE may be defined as a periodically recurring nervous disturbance of which the essential element is headache. But in its classical form it presents a much more complex syndrome; the headache is usually unilateral, and in at least half the cases is preceded by symptoms indicating disorder in localised portions of the cerebral cortex of the side on which the headache is situated; the headache is accompanied by nausea, and after a number of hours vomiting occurs, and this ushers in the last stage of the attack which typically comes to an end in sleep. This symptom-complex is frequently accompanied by a slight mental change and most commonly this takes the form of irritability and depression. The symptoms of localised cerebral disturbance are usually of a sensory nature; hemianopia is the commonest and with it often go scintillating spectra in the dim half of the field; next in frequency come paræsthesiæ in one side of the face and tongue and in the corresponding hand and arm, while auditory disturbances, vertigo, and slight aphasia are not very uncommon. Motor disturbances in migraine are extremely rare, and apart from vague ephemeral pareses of the fingers the only kind of paralysis that is encountered is a palsy of one or more of the oculo-motor nerves. The occurrence of such a palsy during a migraine attack constitutes the so-called ophthalmoplegic migraine. It is only in very rare cases that this complication occurs, but when it does the patients may suffer from it with many of their attacks; the paralysis lasts a few days or even weeks, and diminishes gradually only to be renewed with the next paroxysm. Another atypical form of migraine results from a variation in the quality and perhaps also in the site of the pain, so that instead of being a unilateral headache it becomes a neuralgia in the cheek or temple.

Ætiology and Diagnosis.

Migraine is often hereditary; in a large number of cases it comes on at or before puberty, and in 80–90 per cent. of cases it has begun by the time the subject has reached the age of 25. Many sufferers have their own convictions in regard to its causation, but these views are very divergent, and it must be admitted that we simply do not know the cause or nature of this ailment. There is, however, almost a consensus of opinion that it arises in some way from a functional disorder of the vegetative nervous system; this view accounts for the close association between the onset of attacks and disorders of the alimentary canal, while the pallor of most of the patients during their attacks certainly indicates that the vaso-motor system is involved. If this theory is correct the action on the cerebral cortex whereby the sensory symptoms are produced must be a very indirect one, since the cortical blood-vessels are devoid of vaso-motor nerves. Another theory is that the foramen of Munro on one side becomes blocked and that the cerebral symptoms are a consequence of the distension of the hemisphere that results from the continued secretion of cerebro-spinal fluid into the closed lateral ventricle. Some writers, notably F. G. Crookshank, have regarded migraine as a psycho-neurosis, but this suggestion has not found wide acceptance, and it seems inadequate to account for such a symptom as ophthalmoplegia.

The sensory accompaniments distinguish migraine from other forms of headache, and if they are absent its unilateral distribution and the paroxysmal nature and definite course of the attack usually make its nature apparent. The headache of cerebral tumour or intracranial syphilis is almost always more general, and the patient rarely has such intervals of absolute freedom. A commencing occipital lobe tumour may give rise to attacks of headache with hemianopia and scintillations. but the sudden onset and abrupt cessation of these attacks is unlike the course of migraine. and eventually a convulsive seizure or the onset of papillœdema may make the diagnosis clear. Similar symptoms may occur in certain cases of epilepsy. and here, as in cases of tumour, the occurrence of a fit may show that the ailment is not migraine. The onset of an ocular paralysis in a case of supposed migraine calls for the most careful revision of the diagnosis and a thorough examination of the nervous system, for ophthalmoplegic migraine is a rare condition and the causes of headaches with ophthalmoplegia are many; migrainous neuralgia is commonly mistaken for tic douloureux, but it is not brought on by washing the face, nor by eating or talking; moreover. the pain is less intense and has a less precise distribution: migrainous neuralgia is accompanied by nausea and occurs in subjects who have previously suffered from more typical migraine.

Treatment between the Attacks.

The more specific treatment involves: (1) the use of drugs acting on the vegetative nervous system, (2) general nervous sedatives, and (3) the correction of ocular refractive errors; general measures are also of great importance.

Of the drugs which act on the vegetative nervous system those most in vogue are nitroglycerine and thyroid; calcium lactate has also been credited with good results. Nitroglycerine is best given in the form of liquor trinitrini. of which doses of ½–1 minim are to be taken in acid solution three times a day; it may also be given in the chocolate tablets (each = gr. 1/100), half a tablet or a whole tablet being taken thrice daily. The administration of these doses is to be continued over long periods except during the actual migraine attacks when it should be stopped. Nitroglycerine was extensively used by Gowers, and is still the most widely efficacious remedy; some patients obtain complete relief from it alone. Thyroid, unless there is any indication of thyroid deficiency. is sufficiently exhibited in a dose of grs. 2 of the dry extract taken at bed-time; it probably acts as a general metabolic stimulant. Of the drugs regarded as general nervous sedatives luminal is undoubtedly the best; gr. 1–1½ at night or gr. 1 night and morning. is sufficient. It is best given in tablet because it has a low solubility, and because the soluble compound (with sodium) is not nearly so efficacious. With the less severe types of migraine great reduction in the frequency and severity of the attacks may be obtained from luminal and thyroid without recourse to liquor trinitrini. Bromides are in frequent use and are often combined with salicylates.

The degree to which ocular trouble can be held responsible for migraine is a matter of controversy, but there is no dispute that the sufferers are mostly educated people who read a considerable amount and in whom consequently any astigmatism. heterophoria, or muscle imbalance is likely to be the source of a particular fatigue. It is therefore essential that at the very outset of treatment such conditions should be carefully tested for and, as far as possible, compensated. Gross refractive errors play less part in practice, since among such patients they have nearly always received attention at an early age.

General Measures.

The frequency of attacks is so much affected by the patient's general health that no possible adverse influence can be neglected. The condition of the bowel is naturally the first care. Any tendency to constipation must be effectively treated. and even though constipation be not present benefit is derived from a morning saline. A minute dose of magnesium (or potassium) sulphate, not sufficient in quantity to produce any unpleasant action on the bowel, is perhaps the most efficacious, but *one of the* more palatable effervescent salines may often be substituted. Even a glass of water taken regularly in the morning is helpful. One of the mildly aperient spa waters may be drunk in quantity before meals throughout the day, and in severe cases a course of treatment at a spa is to be recommended. When an attack is thought to be imminent a prompt measure is indicated. such as an effective dose of calomel or a Seidlitz powder. Late hours, stuffy rooms, and fatigue are to be avoided. and sufficient exercise and fresh air must be obtained. The tonic effect of a holiday may procure an unwonted period of freedom; many patients find that unless they have a game of golf regularly at the week-end their headaches increase in frequency and severity, and probably in such cases the exhilaration of the game and its surroundings count at least as much as the exercise. In women anæmia and dysmenorrhœa require careful attention, for the migrainous subject rarely endures a painful menstrual period without an attack. Local infection in the tonsils or in the appendix should be thoroughly treated, and any obstructive trouble in the nose rectified.

The *diet* should be plain: very many patients regard factors in their food as a precipitating cause of their headaches and are aware of the particular circumstances that induce their attacks. It may be an excess of sugar, or an excess of protein, or purin-containing dishes or condiments or alcohol, or almost any single article of food; such causes vary widely from patient to patient, and consequently it is necessary to treat each case individually. In general, the experience of one patient in regard to diet meets with very restricted success when applied to the treatment of another. The limitation of diet is a measure to be applied in moderation, and only one kind of restriction should be enforced at a time; unless the patient's experience gives some other indication the abolition of sweetmeats should be the first to be tried. In considering the influence of such restrictions it must be remembered that the placing of a veto on any single article of diet has the effect of making the patient more careful in regard to his diet as a whole, and consequently benefit may ensue which is not a specific result of the prescribed limitation.

In short, in dealing with migraine, the rule is to review minutely with each patient his diet, conditions of work, and general mode of life, and to endeavour to discover and correct any circumstances by which headache is likely to be induced.

The Attack.

The attack of migraine, once established, is difficult to dispel. If there are prodromal symptoms which the patient recognises the attack may in some cases be aborted or greatly reduced in severity by a dose of calomel or a Seidlitz powder and full doses of aspirin, or one of its congeners, every 2–3 hours. In addition to official remedies there are many analgesics, mostly of the coal-tar group, on the market (e.g., veramon, arcanol, migranin, analgit). Most of them are of value and a patient may find a particular combination which suits him better than the others. These palliatives enable many patients to continue work during the attacks. One of the features of migraine is a peculiar irritability of the sensory systems and all who suffer from the more severe forms go to bed and endeavour to shut out light and noise and to have absolute rest. Some ask only to be left alone, and certainly the first rule is not to disturb the patient with much treatment. The analgesics mentioned may bring a little relief; some patients take strong coffee in addition. some like a compress on the forehead. Little can be done to hasten the climax of the nausea, but when this is reached and vomiting is achieved, sleep usually follows without difficulty. Occasionally chloral or veronal may be required. and in rare cases morphia is used to induce sleep and to enable the patient to retain nourishment in a long-lasting attack.

Special Articles.

CONCERNING THE PROBLEM OF MOUNT EVEREST.

By J. ARGYLL CAMPBELL, M.D., D.Sc. Edin.

(From the National Institute for Medical Research, Hampstead.)

During the expeditions to Mount Everest in 1922 and 1924 it was proved that man can climb, although with difficulty, at an altitude of about 28,000 feet.[1] Norton, Somervell, Mallory, and Irvine reached this height. In addition it was proved that man can live, for some days at least, at altitudes above 23,000 feet (oxygen pressure = 9·5 per cent. atmosphere); several of the climbers spent three or four days above this level, whilst Odell spent ten days at 23,000 feet. Somervell, Norton, Mallory, and Irvine slept for one night at about 26,800 feet. Nevertheless, the exhaustion produced by climbing at 28,000 feet is described as fearful, and progress is very slow indeed. Mallory and Irvine lost their lives whilst climbing somewhere above 28,000 feet. It is possible that they were near the summit, 29,000 feet, where the oxygen pressure in the air is only about 7½ per cent. of an atmosphere. It has yet to be proved whether man can climb at this altitude. In recent experiments with animals [2 3 4] I have proved that some mammals—rabbits, rats, and mice—can live for at least seven days under continuous exposure to oxygen pressure at 7½ per cent. of an atmosphere. The animals were resting at normal temperature (15°–20° C.) and were not exposed to the rigors of chilling winds and very low temperatures, such as the climbers experienced. The outline of one of these experiments is given in Table I.

Table I.

Thirty animals in Messrs. Siebe Gorman's decompression chamber: 6 rabbits, 6 guinea-pigs (g.-pigs), 6 rats, 12 mice. *T. = 15°–20° C.*

Barometer mm. Hg.	Av. O_2 pressure in inspired air.		Approx. altitude corresponding to O_2 pressure.	*Deaths.*	*Duration in* days.
	mm. Hg.	Atmosphere.			
		Per cent.	Feet.		
600	116	16·6	7,000	—	3
440	85	12·1	15,000	2 mice.	7
400	77	11·0	18,000	—	1
375	72	10·3	20,000	6 mice.	6
320	62	8·8	25,000	1 mouse, *6 g.-pigs.*	7
290	56	8·0	27,500	—	1
260	50	7·1	30,000	1 rabbit, 1 mouse.	8

Average loss of weight of survivors = 23·1 per cent.[3]

The animals—6 rabbits, 6 guinea-pigs, 6 rats, and 12 mice—were exposed in a decompression chamber to gradually decreasing oxygen pressure such as might be experienced during a gradual ascent of the mountain. The animals thus had about four weeks to become acclimatised to low oxygen pressure before they were exposed to the lowest pressure (7½ per cent.) equivalent to that at the summit. Of the 30 animals under investigation, only 13—5 rabbits, 6 rats, and 2 mice—survived the experiment and, although they were obviously deteriorating rapidly, they gradually regained normal vigour when again under normal oxygen pressure.

In another experiment 50 normal mice were exposed to low oxygen pressure for 53 days, and on 14 of these days the oxygen pressure was as low as that on the summit of Mount Everest. The barometric pressure was kept about normal in this case; the special closed chamber used has been described elsewhere.[2 3] This experiment was really part of the control for another research to detect the effects of low oxygen pressure on cancer growth in rats and mice; the results for cancer were given in another communication to The Lancet (April 28th, 1928, p. 828). Of the 50 normal mice tested, 21 died (see Table II.) under the effects of the low oxygen pressure and the others were killed for histological examination.

Table II.

Fifty mice exposed to low oxygen pressure for 53 days at normal barometric pressure. T. = 15°–20° C.

Days since beginning of experiment.	Mice alive.	Deaths.	Killed for histological purposes.	Av. O_2 pressure in inspired air.		Average altitude corresponding to O_2 pressure.	Days at Mount Everest level.
				Atmosphere.	mm. Hg.		
				Per cent.		Feet.	
0	50	—	— }	11·6	81	16,000	0
7	50	—	— }				
14	50	—	—	9·8	68	20,000	0
21	50	—	—	9·3	65	22,000	1
28	40	10	—	8·2	57	26,750	3
35	40	—	9	8·3	58	26,500	3
42	29	2	—	8·0	56	27,500	3
49	22	7	2	8·7	61	25,000	1
53	20	2	18	7·2	50	30,000	3
Total ..		21	29	—	—	—	14

Average weight of survivors before experiment = 19·4 g.; after experiment = 15·9 g.; difference = −18·0 per cent.

Numerous other similar experiments were carried out on a monkey, 3 cats, 3 rabbits, 9 rats, and 2 guinea-pigs. Only the rabbits, mice, and rats were able to tolerate oxygen pressure as low as 7½ per cent. for any length of time; the monkey,[3] after a reasonable degree of acclimatisation, was collapsed, although it could be aroused with difficulty. Like the other animals which were unsuccessful, it showed evidence of heart failure, but recovered completely under normal oxygen pressure, regaining its lost weight and growing at the normal rate again.

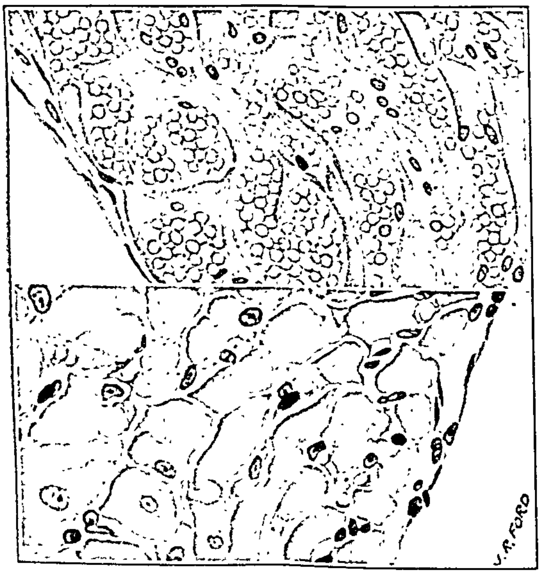
A few details of pathological changes in some of these animals have been described [2 3 4]; confirmation of these earlier results and fuller information from about 100 animals are now available.

Pathological Effects of Prolonged Exposures to Very Low Oxygen Pressure (7½ per cent.).

All the animals which died under very low oxygen pressure revealed extreme congestion of the liver, of parts of the lungs, and of parts of the heart. Marked congestion was also often seen in the spleen, the kidney, the brain, and the suprarenal; but the liver, lungs, and heart were often markedly affected when the other organs showed only moderate changes. Portions of the lungs were sometimes emphysematous. An extreme degree of fatty degeneration was observed in the hearts and livers of rabbits and guinea-pigs,[4] but only a slight degree—if any—in rats and mice. Nevertheless, in all four types of animal the congestion in parts of the heart and in the liver was so great that there was marked atrophy and even necrosis of the cells. *Occasionally œdema* was observed in several organs. The congestion was due to failure of normal forward movement of blood, the capillaries appearing engorged with blood and excessively dilated. Perhaps the dilatation in the first place was to help the heart, or it may have meant failure of vasomotor nervous centres. Such failure might be expected under very low oxygen pressure, but if the heart were able to work efficiently under low oxygen pressure there is no reason why the centres should suffer from oxygen deficiency, since the circulation could be accelerated as in exercise. In some animals the engorgement of the organs was so great that an increase in the blood volume was suspected; in others the congestion was not sufficiently widely distributed to suggest plethora as an embarrassment to the heart. Under low oxygen pressure the red cells increase in number and the viscosity of the blood is thus increased; to counteract this more fluid might be drawn into the circulation, the red cells then increase again, and so on until a plethora results from a vicious cycle. There is also the possibility of the marked dilatation of the capillaries being due in part to the production of histamine-like substances.

The heart muscle-fibres near the epicardium were widely separated from one another by the dilated capillaries and exhibited atrophic changes (see Fig. 1), whilst the liver cells appeared merely as the threads in a network (Fig. 2). The suprarenal sometimes showed atrophy of cortex and medulla, with disappearance of many cells from the latter. The kidney, although sometimes markedly congested, showed but moderate degrees of atrophy and degeneration. In the brain there was often congestion and occasionally disappearance of some of the nerve-cells. Ten of the animals which survived the experiment and were killed for histological purposes showed similar and equally marked changes, but a small majority showed a moderate degree of congestion, while two or three showed scarcely any change from normal; these two or three were apparently able to withstand the very low oxygen pressure. The simplest explanation is that their heart muscle was able to function under very low oxygen tension and to keep the circulation going well. In the animals which succumbed, the symptoms during life and the post-mortem evidence indicated the onset of heart failure as the main cause of inability to tolerate very low oxygen pressure. Undoubtedly all organs must be affected by the abnormally low oxygen pressure, but the supply and pressure of oxygen in the other tissues depend upon the ability of the heart to keep the circulation going strongly. If the heart could do this there was marked power to withstand low oxygen pressure as demonstrated by a few of the animals; if it could not the animals fell by the wayside at an earlier stage with the same pathological changes. These pathological results with animals offer a suitable explanation why climbing at high altitudes leads to fearful exhaustion.

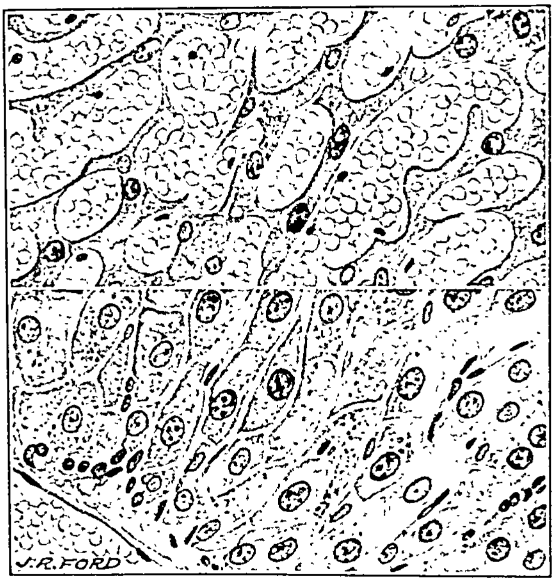
FIG. 1.



Monochrome drawings of heart muscle near the epicardium of a normal mouse (below), and of a mouse failing to tolerate low oxygen pressure. Note engorgement of capillaries, with effects upon muscle-fibres. Hæmatoxylin and eosin (× 450).

Judging from the number of deaths among these testing animals it seems doubtful whether human beings will be able to tolerate such a low oxygen pressure for a period long enough to reach the summit of Mount Everest, and it will be difficult to choose suitable climbers. It is suggested that subjects should be trained for some weeks by spending a few hours daily in decompression chambers and that they should then be tested for their ability to retain their mental and physical vigour in order to carry out the necessary muscular effort while breathing oxygen at about 7½ per cent. of an atmosphere. In this way those who were successful would have the advantage of knowing they could climb under low oxygen pressure such as they would experience on the summit of Mount Everest.

FIG. 2.



Monochrome drawings of liver from a normal mouse (below) and from a mouse failing to tolerate low oxygen pressure; note engorgement of capillaries with atrophy of cells. Hæmatoxylin and eosin (× 450).

Major Hingston [5] states that all the climbers had dilated hearts; their excessive panting on exertion was probably due to the onset of heart failure. They all showed loss of weight and of appetite at high altitudes. Similarly my animals in the present and previous experiments [3] lost on an average 20 per cent. of their weight, and they were young growing animals. Major Hingston states that the climbers with poor appetite preferred sweet foods at very high altitudes, and I found that the addition of glucose (5 per cent.) to the drinking water increased the consumption of fluid. I found that the animals consumed much less water when exposed to low oxygen pressure. Of course, mountaineers experience thirst at great altitudes because of the relatively dry air and the large volume breathed; but my experiments prove that low oxygen pressure itself tends to diminish water consumption. Some of the mice were given alcohol (2 per cent.) in the glucose solution and others adrenalin chloride (1/100,000, Parke, Davis and Co.) freshly dissolved in glucose solution every few days; but none of these substances materially benefited the animals, judging by the average weights of different batches of ten mice.

Acclimatisation to Very Low Oxygen Pressures.

It is not always very clear what is meant by the word acclimatisation. According to Major Hingston,[5] Somervell believed that acclimatisation took place at 21,000 feet even though there was physical deterioration and dilatation of the heart; evidently in this case acclimatisation means absence of the subjective symptoms of mountain sickness. Perhaps acclimatisation is usually taken to mean maintenance of normal appetite leading to normal metabolism and bodyweight.

Dr. J. S. Haldane [6] recently gave it as his opinion that secretion of oxygen by the lung was necessary to explain the great efforts displayed by the 1924 expedition. He holds that in this way the oxygen tension in the tissues is kept near normal in acclimatisation. Prof. Joseph Barcroft [7] supports this view of tissue oxygen tension, but opposes the secretory theory and puts forward various other factors for acclimatisation. My own recent experiments [2,3,4] on tissue oxygen tension, where the oxygen tension in the tissues was actually measured for the first time, gave no support to the opinion that oxygen tension in the tissues is kept near normal; all my animals, including those which acclimatised well, showed a markedly subnormal tissue oxygen tension under very low oxygen pressures in the air. In my opinion acclimatisation means the ability of the tissues, particularly the heart, to tolerate a low oxygen tension and to function normally. Acclimatisation takes place far too rapidly in some cases to be explained by such slow changes as increase of hæmoglobin and of red cells, or alteration of oxygen dissociation curve. It is not argued that increased breathing, increase of hæmoglobin, &c., are not of value when they do occur; no doubt they are, but they are not capable of bringing the oxygen tension in the tissues to normal again whilst under very low oxygen pressures in the air. The main factor deciding the power to tolerate very low oxygen pressure is the heart muscle.

It is well known that short spells of very low oxygen pressure are tolerated by certain individuals—e.g., air pilots and other experimental subjects. Major Hingston records that birds flew up around the camp at high altitudes but did not remain there long. It is the prolonged periods of exposure which slowly work their harmful and more than temporary effects. The longer the climbers are exposed to very low oxygen pressures the smaller will be their chance of reaching the summit, however expert climbers they may be. Perhaps the daily inhalation of oxygen at normal pressure for a few hours—as suggested by Dr. Leonard Hill—when above 15,000 feet might inhibit, to some extent, these evil effects. The failure of oxygen in the previous expeditions was perhaps due to the fact that damage to the heart had already occurred and a short spell of breathing purer oxygen could not be of any great use. What the climbers required was complete rest under higher oxygen pressure for a longer period, and not further climbing efforts at a higher altitude hampered by an oxygen apparatus.

CARLISLE INFIRMARY AND THE FEVER HOSPITAL.—The result of an inquiry by Mr. W. F. Fox, of the Charity Commission, into the question of transferring control of the Fever Hospital to the Carlisle City Corporation has now been announced. It may be recalled (see THE LANCET, June 16th, p. 1239) that the governing body of the Cumberland Infirmary, which is in urgent need of extension, was opposing the transference, as the infirmary would then lose its only feasible means of extension. The Charity Commission reports that the inquiry "failed to disclose any practical alternative to the scheme proposed in respect of the Fever Hospital, or to show that the scheme will place the Infirmary in any worse position than at the present." The Commissioners will therefore proceed to complete and establish the scheme, to the great regret of the infirmary governors.

BRITISH EMPIRE CANCER CAMPAIGN.

ANNUAL REPORT.

THE report of the year's work was presented by the Grand Council of the British Empire Cancer Campaign at the annual meeting held at the House of Lords on July 9th. A steady development of activities is recorded. The number of research workers subsidised had been substantially increased, larger grants have been made to institutions, and new centres have been started, notably in Manchester, Liverpool, and Chester.

The Council in an introductory review of the work in progress comment on the difficulty, familiar to all bodies who propose to subsidise research on a large scale, of finding a sufficient number of suitable workers. They express the hope that the International Conference on Cancer, which will meet under their auspices on July 17th in London, will assist in coördinating existing knowledge of cancer problems by enabling English and foreign workers to exchange views on a common footing. Summaries under appropriate headings of the results of research carried out during the year under the auspices of the campaign appear over the signature of Mr. J. P. Lockhart-Mummery, the honorary editor of the report. These general summaries serve to show how wide is the scope of the investigations being made, but they would be more useful if documented by references to the names of workers or of institutions, or to the pages in the report where results are recorded.

During the year efforts have been directed towards the production of immunity against cancer, and to the perfection of the technique of making records of the behaviour of malignant cells in tissue culture. Chemotherapy and radiotherapy have been tried experimentally and on the human subject. The virus theory put forward by Gye has been critically examined, and the study of carcinogenic substances has been pursued. We select for notice the attempts to produce immunity, the studies of therapeutic agents other than surgery, and work on the virus theory.

Attempts to Produce Immunity.

In the Cancer Research Department of the Middlesex Hospital Dr. S. L. Baker and others have inoculated fowls with emulsions or filtrates of the Rous sarcoma, which have been rendered inactive by heat, formalin, or ultra-violet radiation. No definite or lasting immunity has been thus obtained. Prof. S. Russ and his colleagues, working in the same hospital, found that normal rats can be effectively protected against tumour growth by means of tumour tissue which has been exposed to a suitable dose of radiation; the same tissue which can cause a high degree of protection when fresh can cause some stimulation of tumour growth when autolysed. The production of immunity in this way is a process very sensitive to local conditions and very easily disturbed. Four different types of tumour have been used to produce resistance in rats, two carcinomas and two sarcomas. Rats resistant to one type of sarcoma proved resistant to the other type, and mostly also to a hæmorrhagic quickly-growing carcinoma, but no cross immunity was established between the other carcinoma and the sarcomas. Dr. J. C. Mottram, of the Radium Institute, found that chickens in which skin tumours had been made to disappear by radiation were sometimes immune to subsequent inoculation. At the Lister Institute Dr. T. Lumsden has attempted to produce a tumour vaccine by injecting into a tumour a dilution of formalin just adequate to kill the cells while producing little alteration in their chemical constituents. He states that in the last series of 40 rats thus treated 38 were cured of implanted tumours, and of these 36 were afterwards found to be immune. He suggests that concentrated antiserum may be even more effective than formalin, but it is more difficult to obtain. This form of treatment has not yet been tried on spontaneous tumours except in one case.

A rat with a spontaneous mammary tumour was treated with three inoculations of 2 c.cm. concentrated antiserum from a human subject with breast cancer; the tumour disappeared for four months, but then recurred. Dr. Lumsden hopes to be able to make further trial of this treatment on spontaneously occurring tumours. At the University of Edinburgh Mr. J. J. M. Shaw has attempted to determine whether autogenous epithelial implants will protect mice from the production of tumours by applications of tar. The experiments suggest a slight measure of protection, but are not conclusive. Mr. F. C. Pybus and Mr. H. R. Whitehead, working at Newcastle, failed to demonstrate a serum specific against malignant cells growing in vitro. Mr. Harold Burrows is examining the mode of action of various cytolytic agents in connexion with immunisation.

Tissue Culture.

Besides those who have used the method of tissue culture in their researches on the production of immunity many others are now employing this technique. At the Middlesex Hospital factors influencing the rate of growth of embryo, adult, and malignant tissues are under test, and permanent records are being made by the cinematographic process. At St. Bartholomew's Hospital Dr. Malcolm Donaldson and Dr. R. G. Canti have been studying the action of irradiation respectively on normal and malignant cells in tissue cultures with the cinematographic apparatus designed by the latter. They hope by this means to elucidate the laws governing the disappearance of malignant growth under the action of radium. Mr. E. Neville Wilmer at Manchester has, with Mr. L. P. Kendal, investigated the properties of the growth-activating principles in Witte's peptone. Contrary to the results obtained by Carrel they found that the pure proteose fraction was inactive in saline media.

Therapeutic Methods.

At the Cancer Hospital (Fulham-road) the blood-picture during the clinical application of X rays has been studied. The conclusion is reached that dosage should be controlled by blood-counts, since over-dosage is dangerous. Patients vary in their resistance to radiation, and repeated doses at short intervals appear to exercise little influence on the blood until the "saturation point" is reached, when a sharp diminution of the white cells occurs. The change in the blood is likely to progress when once initiated until a minimum value is arrived at, after which, if no further treatment is given, the blood-picture returns to normal; but if the initial dose has been too large the patient may not recover. The effect of a dose administered at the crucial stage when saturation point has been reached is not easy to calculate, and this is a defect in a mode of treatment which nevertheless is said to be used successfully in an increasing number of patients. The combination of radiations of various wave-lengths is said to be giving encouraging results in the treatment of superficial cancers.

Lead treatment of cancer has been tried at various institutions. Workers at the Middlesex Hospital, after strictly controlled animal experiments, arrived at the conclusion that even when this treatment was begun within five days of the inoculation of a tumour no appreciable effect could be observed on its progress. The result of blood analyses on human patients treated by this method showed a consistent rise in the non-protein-nitrogenous content: in cases examined after death the blood-urea had risen to abnormally high levels. From St. Bartholomew's Hospital the report on this treatment is even more unfavourable. No evidence was obtained that the use of lead by intravenous injection leads to the resorption of neoplastic tissues in man: the average duration of life after treatment was less than the expectation of life without such treatment; and the histological appearances of the growth before and after treatment were indistinguishable. A series of cases treated by lead followed by deep X ray therapy gave more encouraging results, but it is not clear to which of the agents the improvement, when it occurred, was due. In Birmingham a team consisting of Dr. A. P. Thomson and Dr. G. Bulmer, Dr. F. W. Mason Lamb and Mr. G. Sanders, M.Sc., have treated 34 patients with colloidal lead. It is not stated whether these were inoperable when first seen. Two cases were markedly improved, three slightly improved, and five remained stationary; three deaths might be attributed to the treatment. The conclusion reached was that the method is of distinct therapeutic value, and a suggestion is made that the most profitable results will be obtained in cases where palliative incomplete operations have been performed. Dr. F. D. M. Hocking, working at Westminster Hospital, reports favourable changes in cases of carcinoma (not in sarcoma) following injections of thorium and uranium.

Radium.—Among the accounts of treatment is a report from the Westminster Hospital stating that "the treatment of oral cancer by radium has practically displaced surgical treatment." The Cancer Research Committee of the London Association of the Medical Women's Federation have had good results with radium in uterine cancer, especially in cancer of the cervix. St. Bartholomew's Hospital Radiological Cancer Research Department consider that it is too early to draw conclusions from the condition of the cases treated, but they pronounce that in breast cases the results of radium have been "very promising indeed." and that the results in cancer of the upper air passages and uterus show a marked improvement on those reported in previous years. A hopeful sign is that no patient reported "free from signs of disease" in previous reports has yet developed a recurrence. In Birmingham, of 26 cases of inoperable cancer of the rectum treated by radium five are definitely improved, two being completely well at present; the time that has elapsed since the treatment was given is not here recorded.

The Virus Theory.

At the Cancer Hospital Research Institute, under the direction of Prof. A. Leitch, the Rous tumour has been transmitted to fresh fowls by the inoculation into the pectoral muscle of the minced pancreas, free from metastases, from a tumour-bearing bird. Control inoculations with a composite mince of liver, spleen, kidneys, and muscle from infected birds did not yield positive results. In other experiments, following Gye's technique, an extract from the Rous sarcoma was treated with chloroform sufficient to destroy the "virus"; a quantity of this extract was then injected into the pectoral muscles of one side of a fowl and about half of the quantity injected into a corresponding region of the other side, together with a portion of minced pancreatic extract from a normal fowl. Tumours were produced only from the side where pancreas was injected. Since, according to Gye's theory, the chloroformed extract contained only the accessory chemical factor, the cancer virus would have had to be supplied by the normal pancreas. This experiment, therefore, provided evidence against Gye's theory and led to the further study of the active principle. Some support was obtained for the view that the active agent of the Rous sarcoma may be enzymatic in nature. The difficulties of interpretation are increased by the fact that no means exist for separating viruses from enzymes. Workers from the Middlesex Hospital consider that the evidence that the Rous sarcoma is due to a filtrable virus seems good. No definite evidence has been obtained that mammalian tumours contain a virus, though Gye's experiment in which chloroformed Rous tumour filtrate is activated by a "culture" of a mammalian tumour has been repeated. The activating effect of fluid containing pieces of mammalian tumour may be due either to the addition of a ferment, or of some non-specific substances, to an attenuated Rous virus, rather than to the addition of a fresh virus of mammalian origin. In Edinburgh Mr.

C. F. W. Illingworth is carrying out a critical repetition of certain of Dr. Gye's researches.

Financial Position.

Owing to the gift of £10,000 from an anonymous donor the income of the campaign this year has exceeded the expenditure. Attention is drawn to heavy commitments for the future, notably the publication of the *Cancer Review*, which is now a permanent feature of the campaign's work, and has to be provided for over a period of five years at a total estimated cost of £15,000. The cost of the journal for the present year amounted to £2538, administrative expenses to £2676, cost of appeals to £2673; grants to hospital and research workers accounted for £18,158.

The public are reminded in the report that no claim to have discovered anything important bearing on the cure or prevention of cancer is left uninvestigated, and that no proper appeal for assistance is refused without careful consideration.

MATERNITY AND INFANT WELFARE.

NATIONAL CONFERENCE AT GUILDHALL, LONDON JULY 4TH–6TH.

A CONFERENCE promoted by the National Association for the Prevention of Infant Mortality, in coöperation with the M. and C.W. Group of the Society of M.O.H.'s, was held from July 4th to 6th in the Guildhall, London, under the auspices of the Central Council for Infant and Child Welfare. There was a large attendance of delegates including representatives from the Dominions and other countries. The first day of the meeting was devoted to visits to child welfare institutions. The actual conference was carried through in four sessions on the second and third days.

Relative Values.

Sir **ARTHUR STANLEY** presided over the opening session on the relative value of intensive methods employed for the reduction of infant mortality. Sir **GEORGE NEWMAN**, the President of the Conference, in an introductory address, showed how much the movement for the welfare of mothers and children had depended on the pioneer efforts of voluntary workers.

Sir **TRUBY KING** (New Zealand) gave an interesting comparison between Holland and New Zealand. In Amsterdam the infant mortality was about 50, the mortality in the first month was 13, and for the remaining 11 months of the year 37, while the maternal mortality from childbirth was about 2 per 1000 births. In New Zealand the infant mortality was about 42, the mortality in the first month being 28 and in the remaining 11 months 14, and the maternal mortality was 5. New Zealand had concentrated on the child while Holland had concentrated on the mother, and achieved its good maternal and neonatal rates by well-trained midwives and a good obstetrical service. In New Zealand they were now devoting their attention to the obstetrical service, and they hoped that, as a result, before long their total infant mortality-rate would be under 30.

Dr. **ERIC PRITCHARD** (London) referred to the great variation in the neonatal mortality-rates in the various districts in this country as indicating that a large proportion of these deaths were preventable. He referred especially to the competition, promoted by the *Daily News* under the ægis of the National Baby Week Council, among the districts, which could show the largest percentage reduction in the neonatal rate of 1927 when compared with the average rate for the years 1922–26. Of the districts with populations of 100,000 and upwards Leyton won the first prize with a neonatal rate of 18 in 1927 and a percentage reduction of 10; and Bethnal Green won the second prize with a rate of 20 and a percentage reduction of 7. The two highest neonatal rates in this group were South Shields C.B. with a neonatal mortality-rate of 42 and Oldham C.B. with a neonatal mortality-rate of ·48·6. Of the districts with populations between 100,000 and 50,000, Finchley U.D. won the first prize with a neonatal mortality of 12·7 for 1927 and a percentage reduction of nearly 15, and Bath C.B. won the second prize with a neonatal mortality of 21—a percentage reduction of 12. The highest neonatal rates in this group during 1927 were Barnsley with 36 and Wigan with 39. In answer to a questionaire most of the competitors hesitated to attribute the decrease of neonatal mortality to any one particular factor, but suggested a combination of causal factors, such as improved child welfare administration, increased efficiency of health visitors, improved housing, and a better midwifery service. Dr. Pritchard concluded by expressing his strong belief that much more could be done by applying the knowledge we had obtained from the feeding of animals to securing a satisfactory diet for expectant and nursing mothers.

Dr. **S. G. MOORE** (Huddersfield) described the scheme which had been in operation for some years in a special district of Huddersfield and which was now to be applied to the whole borough. The essentials of the scheme are the visitation of expectant mothers and the babies, after they are born, by whole-time women doctors, and an endeavour to secure continuous nursing, day and night, when necessary, for sick babies in their own homes. In 1912–14 the infant mortality-rate in the special district was 111 and in the rest of the borough 101. In 1921–23 the rate in the special district was 72 and in the rest of the borough 80. In 1921–26 the rate in the special district was 69 and in the rest of the borough 79. Among the 4721 women whose pregnancy was notified and supervised during the years 1917 to 1924 the maternal mortality from childbirth was 1·87 per 1000 births, as compared with a maternal mortality of 5·67 for the mothers whose pregnancy was not notified and supervised.

Dr. **A. HAMILTON WOOD** said they had 36 centres in Warwickshire, all under voluntary management, but they needed double the number. He advocated motor transport for the health visitors, the conduct of antenatal clinics by doctors who were not in practice, and more maternity hospitals, and thought it was a great pity that the Ministry, for financial reasons, had been obliged to cut down the supply of free milk for expectant and nursing mothers.

Dr. **T. Y. FINLAY** (Edinburgh) thought that so far antenatal work in Edinburgh had reduced maternal mortality more than neonatal mortality.

Maternal Morbidity.

At the second session was discussed what Lady **BARRETT**, who presided, described as the "failures of midwifery."

Prof. **BECKWITH WHITEHOUSE** (Birmingham) referred to the low maternal mortality-rate of 1·3 per 1000 births attained by the Queen's nurses in their attendance on 55,960 maternity cases during 1927. Certain extern departments of maternity hospitals also had a rate of less than 2. He thought these results were obtained by efficient organisation, antenatal supervision, absence of hasty interference during labour, and surgical cleanliness. He summarised his recommendations as follows: (1) the trained nurse-midwife should attend all normal obstetric cases; (2) antenatal supervision and the decision as to when a case was normal or abnormal was the duty of the medical profession; (3) antenatal centres should be available in all areas, at which the general practitioners should attend to see their own patients and also those submitted by the midwives in the area; (4) the antenatal centres should provide sterilised obstetric outfits, to be paid for by the patients or out of the maternity benefit; (5) panels of obstetric specialists should be available for the help of the practitioner, not only for puerperal pyrexia, but for all complications; (6) in-patient maternity departments should be established in all hospitals for the investigation of difficult antenatal problems and the management of grave obstetrical complications. He thought that normal cases should be attended in the homes and that hospital beds should be chiefly reserved for primiparæ and complicated or "borderland" cases.

Dr. F. T. H. Wood (M.O.H., Bootle) thought it would be difficult to work an antenatal clinic conducted by general practitioners in towns, and Dr. Whitehouse in reply urged the extreme importance of interesting the general practitioner in antenatal work and suggested that Dr. Wood's objection might be met by the holding of more frequent clinics.

Dr. Helen MacMurchy (Canada) said that 641 replies made by the 8000 practitioners of Canada to a Ministry questionaire indicated that many practitioners had solved this question for themselves. One practitioner had had no maternal death in 37 years and many had had no deaths among a series of 1000 cases.

Mr. K. M. Grant (Salford) urged that doctors should work only with trained midwives at confinement cases.

Prof. Louise McIlroy (London) spoke on the great importance of postnatal clinics to ensure that everything possible was done to repair damage left by the confinement. She described a "Discharge card" issued by the Royal Free Hospital to every woman who left the lying-in wards. The card gives particulars of the character of the labour, the condition of the mother and infant on leaving, &c., and is intended to be taken by the patient to any clinic (or doctor) which she may attend subsequently. Most so-called diseases of women were due to confinements. Lacerations were inevitable, but their repair was most important. She believed that cancer of the cervix, which took a larger toll of women's lives than childbirth, could be to some extent prevented by careful postnatal supervision. The antenatal doctor leaves the confinement to the midwife, but the midwife should send the patient back to the doctor for overhaul after the confinement. If each mother was supplied with a card or obstetrical "dossier" recording all her pregnancies and confinements it would save an enormous amount of speculation on the part of medical attendants.

Prof. Pirquet (Vienna), who was invited to speak, referred to the work done by the League of Nations Committee in the investigation of the causes which led to the very different mortality-rates in the various countries. He said that Norway led Europe with an infant mortality of about 30 and that Oslo led also in birth control, but that they had gone too far in this latter respect, the birth-rate being less than a quarter of what it used to be. He could sympathise with birth control after the sixth or seventh child, but not as regards the first. He regarded the tendency to avoid having children as a mere fashion, which would pass away. The birth-rate in France was now going up a little. The resident population of the U.S.A. had few children, but there was some evidence of a change of viewpoint, and the desire for the first child was being put before the desire for a car. One of the important points in which the public needed education was the protection of the lying-in mother and her baby from catarrhal infections brought in by neighbours.

Dr. Esther Rickards said they had the advantage in Tottenham of a unification of the public medical services. The midwives were being induced to send back the mothers to the clinic for postnatal overhaul. One-third of the women examined at the antenatal clinic came back to her about four weeks after confinement and 50 per cent. needed some treatment. Health visitors can also persuade the mothers to come to the clinic. Coöperation with the midwife was most important. Infant cards, school cards, antenatal cards, and confinement dossiers should be passed on, completing the cycle.

Maternal Mortality.

Dr. Eardley Holland (London) opened the discussion on the causes and prevention of maternal mortality at the third session, presided over by Dr. Elwin H. T. Nash. The safening of child-bearing should, he said, be the outstanding problem of public health. In spite of the able reports on the subject issued first by the Local Government Board and more recently by the Ministry, they had not yet captured public opinion. Other countries beat us—for example, Holland, Denmark, Sweden, Norway, and Italy—all with rates under 3 per 1000. Some countries were worse than we were—Switzerland, Germany, and the U.S.A. Sepsis accounted for about 40 per cent. of the deaths and 70 per cent. of the septic cases were complicated labours. He had recently had the opportunity of investigating conditions in Sweden. The Swedish maternal mortality had remained at about 2·5 per 1000 births during the last 25 years, in spite of efforts to reduce it still further. Contracted pelvis was rare in Sweden and toxæmias were less frequent than here. In Sweden the medical curriculum lasted nine years and the medical students had four months' residential training in midwifery in large hospitals manned by experts, in which there were no midwives trained, the medical students doing all the midwifery work. The midwives went through two years' training also in large maternity hospitals in which there were no medical students. The antenatal work in Sweden was done by obstetrical experts. All Swedish mothers were attended by midwives and the doctor was only summoned for complications or to give anæsthetics. The maternity hospitals were splendid and 30 per cent. of the women were confined in them last year. The number of practising midwives was becoming less as more mothers went into hospitals for confinement. Midwives in Sweden have been trained since 1680, their training is founded on a very good education, and the service has great traditions. Both the midwifery and medical professions enjoy much greater prestige in Sweden than in this country. This confidence in the midwives and doctors abolishes the fear towards child-bearing which is so prevalent here and which is inculcated in our prayer-book and certainly affects the proper performance of the function of child-bearing. He thought, if we gradually reorganised our obstetric service on the lines adopted in Sweden, we might ultimately halve our maternal mortality and save 1500 lives of mothers annually in addition to preserving the health of very many more. Up to now our efforts had been utterly futile.

Dr. R. Veitch Clark (M.O.H., Manchester) said that maternal mortality involved maternal morbidity and neonatal mortality, besides being a lamentable destroyer of home and family life. Fifty per cent. of gynæcology was concerned in repairing the damage done by child-bearing. In spite of the fact that Manchester lost half the sunlight available in the neighbourhood, nowadays they only saw rickety deformities in adults, and we could look forward hopefully to the disappearance of pelvic deformity as a cause of death in child-bearing in another generation. The remedies for high maternal mortality—viz., antenatal supervision and a better midwifery service—were rendered difficult to obtain by the fact that the expectant mother does not know she needs them. Nurses, health visitors, and midwives are those who can best educate the mothers. The midwife should be guaranteed her fee if she loses her patient by sending her to the antenatal clinic, and the remuneration of midwives should be raised, if necessary, by subsidies. Investigation in Manchester had shown that privacy for the confinement was impossible in the majority of homes and maternity hospital beds were therefore needed for normal cases. The antenatal centres should be grouped round the larger hospitals. Much further research is required as to the physiology of pregnancy.

Mr. Aleck Bourne (London) was convinced, as a teacher and examiner of midwives, that insufficient stress was laid on the general principles lying behind the practical details. Quite ineffectual solutions of lysol might take the place of cleanly methods. Rubber gloves, judging by the careless way they were used, were regarded as possessing magical properties. The talk about antenatal work was throwing into the background the importance of recognising abnormalities early in labour. One examination of the urine

C. F. W. Illingworth is carrying out a critical repetition of certain of Dr. Gye's researches.

Financial Position.

Owing to the gift of £10,000 from an anonymous donor the income of the campaign this year has exceeded the expenditure. Attention is drawn to heavy commitments for the future, notably the publication of the *Cancer Review*, which is now a permanent feature of the campaign's work, and has to be provided for over a period of five years at a total estimated cost of £15,000. The cost of the journal for the present year amounted to £2538, administrative expenses to £2676, cost of appeals to £2673; grants to hospital and research workers accounted for £18,158.

The public are reminded in the report that no claim to have discovered anything important bearing on the cure or prevention of cancer is left uninvestigated, and that no proper appeal for assistance is refused without careful consideration.

MATERNITY AND INFANT WELFARE.

NATIONAL CONFERENCE AT GUILDHALL, LONDON JULY 4TH–6TH.

A CONFERENCE promoted by the National Association for the Prevention of Infant Mortality, in coöperation with the M. and C.W. Group of the Society of M.O.H.'s, was held from July 4th to 6th in the Guildhall, London, under the auspices of the Central Council for Infant and Child Welfare. There was a large attendance of delegates including representatives from the Dominions and other countries. The first day of the meeting was devoted to visits to child welfare institutions. The actual conference was carried through in four sessions on the second and third days.

Relative Values.

Sir ARTHUR STANLEY presided over the opening session on the relative value of intensive methods employed for the reduction of infant mortality. Sir GEORGE NEWMAN, the President of the Conference, in an introductory address, showed how much the movement for the welfare of mothers and children had depended on the pioneer efforts of voluntary workers.

Sir TRUBY KING (New Zealand) gave an interesting comparison between Holland and New Zealand. In Amsterdam the infant mortality was about 50, the mortality in the first month was 13, and for the remaining 11 months of the year 37, while the maternal mortality from childbirth was about 2 per 1000 births. In New Zealand the infant mortality was about 42, the mortality in the first month being 28 and in the remaining 11 months 14, and the maternal mortality was 5. New Zealand had concentrated on the child while Holland had concentrated on the mother, and achieved its good maternal and neonatal rates by well-trained midwives and a good obstetrical service. In New Zealand they were now devoting their attention to the obstetrical service, and they hoped that, as a result, before long their total infant mortality-rate would be under 30.

Dr. ERIC PRITCHARD (London) referred to the great variation in the neonatal mortality-rates in the various districts in this country as indicating that a large proportion of these deaths were preventable. He referred especially to the competition, promoted by the *Daily News* under the ægis of the National Baby Week Council, among the districts, which could show the largest percentage reduction in the neonatal rate of 1927 when compared with the average rate for the years 1922–26. Of the districts with populations of 100,000 and upwards Leyton won the first prize with a neonatal rate of 18 in 1927 and a percentage reduction of 10; and Bethnal Green won the second prize with a rate of 20 and a percentage reduction of 7. The two highest neonatal rates in this group were South Shields C.B. with a neonatal mortality-rate of 42 and Oldham C.B. with a neonatal mortality-rate of 48·6. Of the districts with populations between 100,000 and 50,000, Finchley U.D. won the first prize with a neonatal mortality of 12·7 for 1927 and a percentage reduction of nearly 15, and Bath C.B. won the second prize with a neonatal mortality of 21—a percentage reduction of 12. The highest neonatal rates in this group during 1927 were Barnsley with 36 and Wigan with 39. In answer to a questionaire most of the competitors hesitated to attribute the decrease of neonatal mortality to any one particular factor, but suggested a combination of causal factors, such as improved child welfare administration, increased efficiency of health visitors, improved housing, and a better midwifery service. Dr. Pritchard concluded by expressing his strong belief that much more could be done by applying the knowledge we had obtained from the feeding of animals to securing a satisfactory diet for expectant and nursing mothers.

Dr. S. G. MOORE (Huddersfield) described the scheme which had been in operation for some years in a special district of Huddersfield and which was now to be applied to the whole borough. The essentials of the scheme are the visitation of expectant mothers and the babies, after they are born, by whole-time women doctors, and an endeavour to secure continuous nursing, day and night, when necessary, for sick babies in their own homes. In 1912–14 the infant mortality-rate in the special district was 111 and in the rest of the borough 101. In 1921–23 the rate in the special district was 72 and in the rest of the borough 80. In 1921–26 the rate in the special district was 69 and in the rest of the borough 79. Among the 4721 women whose pregnancy was notified and supervised during the years 1917 to 1924 the maternal mortality from childbirth was 1·87 per 1000 births, as compared with a maternal mortality of 5·67 for the mothers whose pregnancy was not notified and supervised.

Dr. A. HAMILTON WOOD said they had 36 centres in Warwickshire, all under voluntary management, but they needed double the number. He advocated motor transport for the health visitors, the conduct of antenatal clinics by doctors who were not in practice, and more maternity hospitals, and thought it was a great pity that the Ministry, for financial reasons, had been obliged to cut down the supply of free milk for expectant and nursing mothers.

Dr. T. Y. FINLAY (Edinburgh) thought that so far antenatal work in Edinburgh had reduced maternal mortality more than neonatal mortality.

Maternal Morbidity.

At the second session was discussed what Lady BARRETT, who presided, described as the "failures of midwifery."

Prof. BECKWITH WHITEHOUSE (Birmingham) referred to the low maternal mortality-rate of 1·3 per 1000 births attained by the Queen's nurses in their attendance on 55,960 maternity cases during 1927. Certain extern departments of maternity hospitals also had a rate of less than 2. He thought these results were obtained by efficient organisation, antenatal supervision, absence of hasty interference during labour, and surgical cleanliness. He summarised his recommendations as follows: (1) the trained nurse-midwife should attend all normal obstetric cases; (2) antenatal supervision and the decision as to when a case was normal or abnormal was the duty of the medical profession; (3) antenatal centres should be available in all areas, at which the general practitioners should attend to see their own patients and also those submitted by the midwives in the area; (4) the antenatal centres should provide sterilised obstetric outfits, to be paid for by the patients or out of the maternity benefit; (5) panels of obstetric specialists should be available for the help of the practitioner, not only for puerperal pyrexia, but for all complications; (6) in-patient maternity departments should be established in all hospitals for the investigation of difficult antenatal problems and the management of grave obstetrical complications. He thought that

UNITED STATES OF AMERICA.

(BY AN OCCASIONAL CORRESPONDENT.)

The Minneapolis Meeting: Presidential Address.

THE seventy-ninth annual session of the American Medical Association, held last month at Minneapolis, Minnesota, was made notable by the presidential address by Dr. W. S. Thayer, of Baltimore, an address showing great breadth of vision and couched in beautiful language. Dr. Thayer reminded his audience that they represented a profession organised for no selfish end, but, as their constitution has it, " . . . to promote the science and art of medicine and the betterment of public health." Since it is the unusual which constitutes news, the self-seeking commercialised doctor is the one who is shown most often in the newspapers. Too many of us generalise carelessly from what we read in the papers. " I am not likely to forget," he said, " the response given by a large assembly of physicians in London when the Lord Chief Justice, in a graceful address, spoke of the fundamental likeness between the profession of law and that of medicine, each humane and devoted to the alleviation of the ills of mankind. The audience laughed. I was mortified and pained." Nevertheless, continued Dr. Thayer, to be a physician to-day is a privilege. Few greater opportunities are given for immediate service to our fellows, and for that intimate association with men and women which cultivates human charity and sympathy and understanding and tolerance, one of the most beautiful of words, and temperance, one of the most abused. To make the most of his opportunities a doctor must have a basic education—one that should enable him to appreciate that which is fine in life, in art, and in literature.

Standard of Medical Education.

Through the efforts of the American Medical Association, with its council on education, and the generous assistance of the foundations, the standards of education in the profession have been materially raised until to-day the opportunities for medical education in America, fundamental and post-graduate, are second to none.

> " Recently," Dr. Thayer remarked, " we have met with rather severe criticism in the delightful, although somewhat acrid, address of Sir Andrew Macphail,[1] who bitterly complains that the raising of our standards of admission to schools of medicine is flooding some of the institutions of a sister country with undesirable men. To which one can only reply that we are truly very sorry. We should be only too happy to deliver him from the plague of locusts from which we have been delivered ourselves. We did not mean to turn the cloud in his direction. But would he ask us to take them back? "

The Full-time Plan.

There has been considerable criticism of the so-called full-time plan in this country which did not fail to find some expression at this session of the House of Delegates. Dr. Thayer, however, deprived the critics of most of their thunder by pointing to three main misconceptions on which criticism has been based. It has been said that in some schools a professor is debarred from private consultation. Dr. Thayer knows of no school of which this is true. The understanding that exists in some schools that fees for private consultation shall be turned into the budget of the professor's department has been denounced as the practice of medicine by an institution. This aspect of the plan, Dr. Thayer points out, is in any case a detail, and in no sense a vital principle. Third, and most important, is the misconception that it is the ultimate ideal of the university school of medicine to place clinical teaching in the sole hands of university professors.

Early Specialisation.

Turning to the content of the four years' course in medicine, Dr. Thayer suggested that the attempt has been made to crowd too much subject matter into these years. The medical school is not the place for the training of specialists, nor can one emerge from a school of medicine a skilled surgeon. The specialist who has not had a good basic medical training is a danger to society. Too early specialisation is one of the great faults of modern American education. The speaker suggested that those responsible for the curriculum of the nurses' fundamental course are perhaps making the same kind of mistake. The tendency of modern practice is more and more towards specialisation and organisation, and away from the obviously desirable intimate contact between physician and patient. This is in line with the trend of society in other fields, but it raises problems of great importance to the profession. In seeking solutions there are certain fundamental truths to be remembered: " We have," said Dr. Thayer, " duties as physicians towards our patients, to treat them when ill, to advise them lest they become ill, and to the public lest the sickness of our patients becomes a menace to the public health. We have duties also as members of the public who are specially informed and so specially responsible to see that our public health officials are men of high character and adequate training."

The attendance at this session of the meeting was almost 5000, and the scientific exhibit easily the largest and most successful on record. The presidential address and most of the scientific papers read at the session will be fully reported in the journal of the Association.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Housing Conditions in Edinburgh.

THE chief sanitary inspector for Edinburgh, in his annual report for the year 1927, remarks on the progressive policy of the local authority in connexion with slum clearance and housing improvement. Much still remains to be done in improving the housing conditions in many parts of the city. A recent survey showed that there were no less than 5035 houses that could be classified as unfit for habitation. These are mainly situated in the central and more congested parts of the city, but there are also large groups in the more suburban areas. Of the total number, 2243 are one-apartment houses, 2327 contain two apartments, 370 three apartments, and the remainder four or more apartments. Many of these houses have been listed for inclusion in future improvement schemes. If the progress made during the past few years is maintained the whole of these houses could be swept away in a comparatively short period. It has been found that to obtain the best results constant supervision of the occupiers of the new houses is essential. Accordingly, in addition to the routine inspection, arrangements are being made for the systematic visitation of the houses by an experienced inspectress who is to devote special attention to backward tenants. These visits have already achieved good results in improving the habits of the people.

In connexion with this report, it is interesting to note that the Board of Management of the Edinburgh Welfare Housing Scheme have recently issued a special appeal for financial assistance in connexion with the housing scheme which they intend to inaugurate in Edinburgh. They aim at a sum of £25,000 to £30,000, to be raised partly by voluntary gifts and partly on debenture loan. If such a sum were raised, or even, to start with, a smaller amount of £7000–£8000, an experimental block of suitable houses could be provided, which would be let at about 8s. 6d. a week, inclusive of rates. The houses, at the seventh month was of little or no use. The urine should be tested every fortnight during the last two months of pregnancy, however fit and healthy the patient appeared to be. The occurrence of hæmorrhage, however slight, during pregnancy, was not always regarded seriously enough. The midwife should be paid better and her status advanced.

---

At the fourth session Dr. JANE TURNBULL (Ministry of Health) described possible administrative arrangements for the unmarried mother and her child.

MEDICINE AND THE LAW.

Medical Confidence (Attempted Suicide).

AT an inquest at Eastbourne, held at the end of last month, upon the body of a man who met his death on Beachy Head, Dr. R. R. Pirrie stated that two years ago he was called in to see the deceased, who had been found unconscious in a gas-filled bathroom. Asked by the coroner if it was not usual in such cases to report the occurrence to the police, Dr. Pirrie replied in the negative. "From the legal point of view," pursued the coroner, "you may be guilty of being an accessory in not notifying a case of attempted suicide?" "Yes," replied the witness, "but I look at it only from the medical point of view; I am prepared to risk being charged as an accessory; in this case the man recovered and I warned the family." In bringing in a verdict of "suicide while of unsound mind," the jury added as a rider that they thought it would have been as well if the doctor had reported the previous incident. Unperturbed by this declaration, which he described as "purely a pious resolution and not part of the verdict," Dr. Pirrie rejoined that a practitioner has a duty to his patients and that it is not his duty to report such a case to the police.

There can be no doubt that the medical profession will approve their colleague's action and statement of principle in this matter. The patient required treatment, not prosecution. The jury, perhaps, held the mistaken view that medical privilege is claimed and maintained in order to save doctors the trouble of taking part in police proceedings. Medical privilege exists in the interests of the patient. The patients, or their families, require the best medical advice and treatment at the moment, and frank disclosure of all the facts may be necessary in order that the medical assistance may be invoked to the best advantage. There will necessarily be some hesitation on the part of the family in these cases if it is possible (or indeed probable) that the doctor may regard it as his duty to set the police in motion and to furnish them with information not intended to be so applied. There may be occasions when a doctor may have the duty of disclosing his knowledge of a crime, or at any rate of putting such moral pressure upon the criminal as he may deem proper with a view to prevention or confession. One case differs from another and a general statement of professional propriety is difficult; but the duty to the patient comes first. In the Eastbourne case Dr. Pirrie's warning to the relatives was of more practical value than a notice to the police. Action by the police might well have aggravated the patient's condition.

Consideration for Medical Witnesses.

By the courtesy of the courts it has been customary to give special consideration to medical practitioners when called as witnesses. It has been realised that the nature of their duties makes it desirable not to keep them in attendance in courts of law longer than necessary, and it has been found possible sometimes to interpose their evidence out of its turn and usually to release them at the earliest moment. It need not be assumed that this convenient course is to be interrupted merely because of some observations of Mr. Justice Horridge at Hereford Assizes last month. Asked by counsel if a country doctor, who had given his evidence, might be allowed to leave the court, the judge is reported to have replied that doctors were very useful people, but they seemed to think that the administration of justice was entirely subservient to their convenience. "There may be one or two questions I want to ask: he must wait." The court, we are told, then adjourned for lunch. No witness, whether medical or otherwise, would regard it as unreasonable that he should remain in attendance until the court had heard the whole of his evidence. Medical witnesses, however, are justified in asking leave to return to their professional duties as soon as their evidence has been fully given unless, of course, the case is one in which they have undertaken to be present throughout and to advise upon the evidence given by others. A proper application to the judge, deferentially submitted, will usually receive a courteous answer. The remarks of Mr. Justice Horridge may either be dismissed as not very seriously meant, or else discounted as mere obiter dicta.

Criticisms of Coroners Acts.

Fresh criticism has recently been directed at the amendment in the law of coroners made in 1926, whereby inquests can be dispensed with. Such cases fall into two classes. First, there are the deaths where the coroner, after his own private inquiries and without any post-mortem examination, has satisfied himself that no inquest is necessary; he then informs the doctor in attendance on the deceased that he sees no objection to the cause of death being certified as suggested. Secondly, there are the "no inquest" cases, within Section 21 of the 1926 Act, where the coroner (1) believes that a post-mortem examination may prove an inquest to be unnecessary, (2) asks a doctor to make a post-mortem examination and report under the new statutory power, and (3) being thereby satisfied that an inquest is unnecessary, sends the registrar "a certificate under his hand stating the cause of death as disclosed by the report." The report in the latter case is not, of course, given upon oath, and those who are critical of the Scottish system of inquiry (shorn of the publicity which the inquest ensures in England) have not hesitated to comment on the change. Dr. F. J. Waldo, in his evidence before the Home Office Committee on Coroners, once laid down the principle that, if a post-mortem examination be necessary, a public inquest with the witnesses on oath, and in the presence of the relatives, was equally necessary. Parliament, however, in 1926 gave the coroners a discretion in the matter, carefully guarded (subs. (3) of Section 21) by the saving clause that the new provision should not be construed as authorising a coroner to dispense with an inquest in any case where there was reasonable cause to suspect that the deceased had died either a violent or unnatural death, or had died in prison or in certain other special circumstances. If the country has thus —through Parliament—shown this sign of confidence in coroners and the medical profession, those who are so trusted need not repudiate their responsibility. If that confidence is found to have been too lightly given, public opinion would doubtless insist on a change in the law. Meanwhile, there is all the greater obligation upon members of the medical profession to be scrupulously careful and exact in matters of death certification. Solicitors, of whom a high standard is expected in proceedings where large sums of money may be at stake, are fortified in the discharge of their duties by the knowledge that they are, by statute, "officers of the Supreme Court." The medical profession has an even greater responsibility.

THE DUCHESS OF YORK AT HOSPITALS.—On Tuesday in last week the Duchess of York opened a new fresh-air ward and an operating theatre at the St. Nicholas Hospital for Crippled Children at Pyrford, Surrey. Also last week the Duke and Duchess opened an extension of the Queen Alexandra Memorial Hospital at Weston-super-Mare which, with its equipment, has cost £50,000.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Average elementary school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.†
Bedfordshire	—*	—*	4,262	1,572	18·65
Cumberland	—*	—*	7,862	12,593	20·0
Torquay	3,751	3,259	1,339	5,546	21·0

* Not given. † Excluding dental defects and uncleanliness.

Bedfordshire.

THE value of medical inspection is greatly lessened if no treatment clinics exist where parents can obtain advice and minor ailments receive medical attention. Home visits by the nurses are a valuable adjunct to such clinics but can never satisfactorily replace them. It is therefore disappointing to note under Table IV., "Return of defects treated during the year," that no minor ailment has been treated in Bedfordshire under the council's scheme; this presumably means that no minor ailment clinics exist in this county. The school medical staff consists of Dr. R. T. Herdman, S.M.O., and deputy M.O.H., one school dentist, Mr. F. S. Cooper, and one school nurse.

Dr. Herdman remarks that the health of the children seems to be less good this year than it was last year; he attributes the deterioration partly to an epidemic of influenza in the beginning of 1927 and to the sunless summer and autumn. It is clear, however, that his department is understaffed and that the county lacks the facilities on which some of its neighbours rely for the promotion and maintenance of good health in school-children. Dr. Herdman, working single-handed, cannot do impossibilities, and his dental colleague, Mr. Cooper, obviously finds it increasingly difficult to keep pace with his work. It is curious to find treatment facilities so inadequate. There are apparently no special schools of any kind, and no mention is made of open-air schools or orthopædic schemes. This is surprising and inconsistent, for in other directions great efforts seem to be made on modern lines. For example, the senior scholars who are transported from smaller villages to larger centres there receive a good hot mid-day meal, which is cooked, served, and cleared away by the children; moreover, efforts are made to supply dry stockings and slippers for children who have walked long distances to school.

Cumberland.

Dr. F. H. Morison, M.O.H. and S.M.O., explains that the county is divided into six areas, each in the charge of a medical officer responsible for the whole of the work in the area. He stresses the importance of coördination; in Cumberland record cards of the welfare centres are passed on to the schools and show that the percentage of defects in the entrants would be considerably reduced if it were possible to examine and treat all the infants before they came to school. The proportion of entrants requiring treatment this year is three times as high as last year. These children were for the most part born in 1922, which year had a relatively high infantile mortality-rate in the county and a correspondingly high sickness-rate in the next four years of life.

Dr. Morison discusses in a broad-minded way the problem of tonsils and adenoids, citing a case where the prosecution of the parents by the N.S.P.C.C. for refusing treatment aroused hostile comment. He states that he has always laid down the principle that the mere presence of enlarged tonsils and adenoids is not necessarily an indication for operation, but that in certain cases, particularly those with ear symptoms, it is essential to secure their removal. In the particular instance where action was taken, it was the opinion of three members of the school medical staff and of the family doctor that the operation was urgently needed. Hospital accommodation being inadequate, some cases of surgical tuberculosis have been nursed in frames in their own homes, the children being visited once a week by the orthopædic after-care sister and once in four months by one or other of the visiting staff from Windermere. Advantages claimed for this system are (1) considerable saving in expense (a case of spinal caries in hospital may cost as much as £250); (2) the children can start treatment at once without waiting for a hospital vacancy; and (3) hospital beds are left free for the admission of non-tuberculous cripples, who can be dealt with in a much shorter time. It is admitted that the procedure is often impracticable—in rural areas where close supervision is impossible, where parents are not able to coöperate properly or to provide extra food, and where home conditions do not allow open-air treatment. To us it seems that the system may be of some value as a temporary device but not as a satisfactory substitute for more hospital accommodation, which seems to be urgently needed.

Further reports are given on the benefits of iodine in goitre. Dr. Kenneth Fraser has been elected a Fellow of the Royal Society of Edinburgh for his valuable work in this connexion. This year for the first time calcium is also being administered in the hope of improving the results of treatment.

Torquay.

The M.O.H., Dr. T. Dunlop, introduces the report by Dr. J. V. A. Simpson, assistant S.M.O.

The arrangements for the coördination of the work of the school medical service with that of the health department are satisfactory; and the same medical officer who carries out the routine school work attends the maternity and child welfare centres and thus supervises the health of the children from birth right up to school-leaving age. All the facilities for treatment are available for the pre-school child, including the dental service. The good results of Mr. T. G. Fenton's operations for removal of tonsils and adenoids at the Torbay Hospital are recorded. All cases are seen after operation by the medical officer and instructions are given as to the after-care of the child. Dr. Simpson, who is responsible for this report, would prefer an arrangement whereby hospital after-care could be provided for at least 24 hours; and possibly this may be secured when the new hospital is erected. Cripple children for some years past have been sent to special hospitals in London, Bristol, Alton, and elsewhere. No child failed to receive treatment except when parents refused it (two cases). During the past year a comprehensive orthopædic scheme for the county of Devon has been inaugurated and the Torquay authority is coöperating in this. The school clinic is used as the local orthopædic centre once a week and Mr. Brennan Dyball visits it once a month. The year at the open-air school has been highly successful; during the summer a complete set of baths, including shower baths, was installed. The climate of Torquay is so mild that the children can be out in the open air on more occasions than in most other towns in the kingdom; rheumatic children are apparently receiving much benefit from this school.

Dr. Simpson is using the kata-thermometer for estimating the adequacy of ventilation in existing schools and in those being reconstructed. He is also continuing his research into standards of physical fitness of schoolboys and is opening a new line of investigation on the measurement of the ultra-violet rays of the atmosphere under the guidance of Dr. Leonard Hill.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 30TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 219 (last week, 230); scarlet fever, 1639; diphtheria, 903; enteric fever, 37; pneumonia, 757; puerperal fever, 39; puerperal pyrexia, 103; cerebro-spinal when built, would be related to the child welfare activities, municipal and voluntary, of the city, just as many other child welfare activities are already related: the tenants would be selected in view of the need of benefit to young children in the families of the less well-paid wage-earner.

The Effect of Milk on School-children.

The delegates to the World's Dairy Congress held a conference in Edinburgh on July 5th. In the absence of Sir Leslie Mackenzie, Dr. Gerald Leighton, of the Scottish Board of Health, submitted a paper on Milk Consumption and the Growth of School-children, based on experimental findings (see THE LANCET, 1928, i., 202). In November, 1926, the Scottish Board of Health set up a committee to test the effect on 1400 school-children in Peterhead, Aberdeen, Dundee, Edinburgh, Glasgow, Paisley, and Greenock, of a daily ration of milk in addition to their ordinary diet. The experiment has been carefully devised to test the nutrition value of milk, separated milk, and a control food of equal caloric value; the ages of the children tested were from 5 to 13 years. All the children lived at home under the ordinary conditions of Scottish working-class families. The investigation is still in progress, but from the data already available the following conclusions could be drawn:—

(1) The addition of milk to the diet of children of school age during the period under review has been accompanied by an increased rate of growth as indicated by an increase in both height and weight of 20 per cent. greater than that in children not receiving the extra milk.

(2) This increase in the rate of growth has been accompanied by an improvement in the general condition of many of the children receiving milk.

(3) Separated milk is of great value for promoting growth. Its nutritive value for children of school age would appear to be underestimated.

The reports indicated that the children receiving milk appeared to be in better general condition than those who did not receive it. On the whole they had glossier hair, clearer complexions, and even held themselves more erect. The most marked improvement was shown in those children who had been in poor condition at the beginning of the investigation.

Award of the Neiller Prize.

On July 2nd, at a meeting of the Royal Society of Edinburgh, Principal Sir Alfred Ewing, the President, presented the Neiller prize for the period 1925–27 to Prof. Arthur Robinson, professor of anatomy in the University of Edinburgh. The President recalled the fact that, early in his career as an anatomist, Prof. Robinson turned his attention to problems of mammalian embryology, and his first work on the subject was published in 1888. Since that time a series of important papers had appeared from his pen dealing, for the most part, with the development of individual organs in man and other mammals. Of special importance and value were those papers dealing with the early stages of development of mammalian ova. Two of the important conclusions, formulated on the evidence relating to ovarian follicles in the ferret, were afterwards verified in other mammals by the experiments of Prof. Edgar Allen, of the University of Missouri, and by other investigators. During the study of the follicles, Robinson's attention was drawn to the occurrence of prenatal death; with the aid of his own material, supplemented by data provided by the Board of Agriculture for Scotland, he was able to prove that prenatal death occurred with great frequency from causes other than external agencies. The Neiller prize was awarded to him for his recent work in comparative mammalian embryology, and in recognition of his published work extending over a period of 40 years.

Academic News.

The Court of the University of Edinburgh have approved a scheme of rearrangement of the curriculum of medical students in their third year by which the courses now given in two terms will be spread over three. This applies to the systematic courses in medicine and surgery, and to the theoretical and practical courses in pathology, bacteriology, materia medica, and therapeutics. The class examinations will be rearranged accordingly. No increase, either of the total number of meetings of the classes or of the amount of fees payable by the students, is involved.

In consequence of the rearrangement of the curriculum for the Diploma in Tropical Medicine and Hygiene, the diploma is now recognised as a qualification for the posts of junior public health officer in the Colonial Medical Service.

At the recent graduation ceremony at the University of St. Andrews, the Principal referred to the scheme for providing residential entrance scholarships. When the system was fully operative, he said, a steady succession of selected students, unharassed by financial anxiety, would have the opportunity of a Scottish University education, supplemented by the benefits of collegiate residence. The list of these scholarships had recently been increased by an additional award. The firm of Messrs. Tullis, Russell and Co., to which Dr. David Russell belonged, had agreed to contribute £100 annually towards the maintenance of a scholar at St. Andrews, preference to be given to students coming from central Fifeshire.

Public Health Services.

ANOTHER CASE OF ALLEGED OVER-PRESCRIBING BY A PANEL PRACTITIONER.

THE East Sussex Insurance Committee at its meeting on July 3rd had before it a report from its Medical Service Subcommittee dealing with the investigation of prescribing by insurance practitioners and the effect on the medical service of the action of the Regional Medical Officer of the Ministry of Health in criticising the prescribing of a doctor in East Sussex. The facts were similar to those stated in a previous case, some particulars of which were given in THE LANCET of April 14th last (p. 776). It appears that as the result of objection taken by the R.M.O. on general grounds to the cost of a certain proprietary preparation of colloidal iron combined with malt extract, the doctor in question had ceased to order it for his insured patients. The question was raised by a patient who was accepted by the doctor after the period with which the R.M.O. was dealing, so that the latter could not have had before him details of the particular case.

Reviewing the facts, the subcommittee states its opinion that this case confirms the impression derived from the previous case—namely, that the action of the R.M.O. has had the effect of unduly restricting the discretion of medical practitioners in prescribing medicines for their patients, and has tended to create an impression that the insurance medical service is inferior to that rendered to private patients. The procedure laid down by the Regulations in regard to the investigation of prescribing, the rights thereunder both of practitioners and insured persons, and the duties of practitioners, were fully set out in the previous report, and it appears that the statements made and conclusions drawn in that report have not been challenged. The subcommittee therefore recommends the Insurance Committee to inform the practitioner that, in the opinion of the Committee, he should not cease to prescribe for his insurance patients drugs which he believes to be reasonably necessary for their adequate treatment, unless and until the Panel Committee, or the appropriate tribunal on appeal, has decided that the supply of these drugs imposes a cost upon insurance funds which is in excess of what is reasonably necessary for such adequate treatment.

It was decided to raise the question of the principles involved at the meeting of the National Association of Insurance Committees to be held in London next October.

and difficulties of the general medical practitioner. Having been approached on the matter, we venture to solicit the support of the profession as two general practitioners representing industrial and rural areas respectively. We are both in the active pursuit of our profession, and have had a good deal of experience of administrative and medico-political work, which we hope would be of value if the profession should see fit to endorse our candidature. One of us (J. W. Bone) has had 32 years in general practice, private and contract, in the industrial area of Luton, has served on the Insurance Acts Committee for five years, and at the present time has the honour to be a member of the Council of the British Medical Association and chairman of its Medico-Political Committee. The other (E. K. Le Fleming) is familiar with other aspects of private and contract practice through 27 years' work in the rural area of Wimborne; whilst in addition to serving on the Council of the British Medical Association and the Insurance Acts Committee he has been honoured by the confidence of the insurance practitioners for the past five years as chairman of the Conference of Local Medical and Panel Committees of the United Kingdom.

Our experience in interpreting the collective views of our fellow practitioners and our willingness to devote whatever time and energy may be necessary to the proper fulfilment of the duties of a Direct Representative embolden us to solicit the support of the profession generally.

We are, Sirs, yours faithfully,
JOHN W. BONE.
July 7th, 1928. E. K. LE FLEMING.

NASO-PHARYNGEAL INFECTIONS AND EPIDEMIC JAUNDICE.

To the Editor of THE LANCET.

SIR,—In your issue of June 30th you publish a report of a discussion on naso-pharyngeal epidemics in public schools and an interesting leading article on epidemic jaundice in Great Britain. I have already in communications to the medical journals expressed my views as to the ætiology of the common cold, pointing out that the bacteriological aspect of these conditions does not cover the whole question; in fact, that bacteria may not be the primary agent at all, but that there is an underlying biochemical aspect which may be more essential. Organisms which were formerly harmless saprophytes may become pathogenic and infective, as a result of the disturbed biochemistry of the intestine, liver, and blood stream. Routine examination of the urine of people in ill-health has shown me the frequent occurrence, about and prior to a catarrhal season, of cases showing evidence of disturbed intestinal hepatic function, as indicated by the presence of indican, bile oxalates, and other bodies in the urine. The finding of similar evidence in many patients with catarrhal colds (probably these might be regarded as carriers) led me to think that the metabolic disturbance was the underlying cause of the activation of the organisms in the nose and throat. It is difficult to be dogmatic on this point, since one is not called to see these patients until the catarrhal attack develops; but I have had suggestive cases. One in particular who came to me in the height of summer because he was out of sorts. Examination did not reveal much wrong objectively, except that the urine contained bile. Treatment directed to this condition—ammonium chloride with alkalies—resulted on the third or fourth day after in his developing an acute fulminating catarrhal cold.

Recent American writers have been leaning to this metabolic aspect of the common cold and have claimed that it is due to a mild acidosis; and that they could precipitate an attack by the administration of calcium chloride or ammonium chloride. One cannot subscribe to this view entirely, since many patients take these drugs without evincing any signs of a cold; but their exhibition, when there is an underlying hepatic disturbance, may precipitate an attack.

There is probably some disturbance of the blood calcium as well in patients who get colds. Dr. J. A. Glover evidently had this metabolic aspect of the question in view when he recommended the inclusion in the diet of oranges, vegetables, salads, and watercress. The border-line between these cases of colds with disturbed hepatic function and those of epidemic catarrhal jaundice seems to me slight. I do not refer to those cases of jaundice definitely due to the *Leptospira icterohæmorrhagiæ*. I agree with Buchanan and Ross, quoted in your leading article, when they propose a bacteriological examination of the naso-pharynx and intestine in cases of epidemic jaundice. I would go further and suggest that not only bacteriological but biochemical investigation is required. In epidemics of catarrhal colds, or influenza, I have often wondered to what extent the jaundice associated with some of those cases was primarily due to the catarrhal organisms, or to a previous hepatic disturbance caused by some bowel organism—e.g., *B. coli*, which has become pathogenic. It is not easy to explain the fact that organisms in the nose and throat seem only sometimes to become pathogenic. My reading of it is that the soil has been prepared for them by metabolic and biochemical disturbances through atmospheric conditions, improper diet, overcrowding, insufficient fresh air and exercise, so that it is easy for activated organisms to find suitable soil when propagated by droplet infection. This droplet infection does not explain the numerous cases of colds which seem to spring up perhaps on the same day, at the very start of a catarrhal season, often in scattered parts of the town and country, and in people who have not been exposed to infection, but suggests auto-activation. The special frequency of post-operative pneumonia in cases of gall-bladder disease, gastric and duodenal ulcers, where the toxæmia factor is always more or less in evidence, is an allied problem which demands investigation.

I am, Sir, yours faithfully,
R. CHALMERS, M.D., F.R.C.S.E.
Darlington, June 30th, 1928.

"MANSON HOUSE."

To the Editor of THE LANCET.

SIR,—In the report in your issue of June 30th on the twenty-first anniversary dinner of this society Dr. Andrew Balfour is quoted as saying that "over £3000 had been raised towards the provision of a manson house for the Society." The verbatim report before me reads, "I should like to speak of the Manson Fund to provide what is going to be called possibly 'Manson House.' I say possibly because there is a distinguished member of our Council who has so little faith in the sobriety of his fellow Fellows that he feels that 'Manson House' might be mistaken for the building near the Bank or some celestial habitation, and he has proposed that it should be called 'Patrick Manson House' to prevent any such difficulty. I hope it will be called 'Patrick Manson House.'" Comment is not required.

I am, Sir, yours faithfully,
CLAYTON LANE,
Joint. Hon. Secretary, Royal Society of Tropical Medicine and Hygiene.
11, Chandos-street, Cavendish-square, London, W.,
July 4th, 1928.

LIVER TREATMENT IN PERNICIOUS ANÆMIA.

To the Editor of THE LANCET.

SIR,—Dr. J. H. Anderson in your issue of March 31st (p. 674) wishes to know if Orientals have long been using powdered liver for pernicious anæmia. It may interest him to learn that desiccated flesh of a carnivorous crow has for ages been used by the Indian *vaid* (herbalist) for a condition allied to fever, 9 ; acute poliomyelitis, 4 ; encephalitis lethargica, 20 ; dysentery, 7 ; ophthalmia neonatorum, 111. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 20 counties : London, 12 ; Bedford, 2 ; Derby, 23 ; Durham, 49 ; Lancaster, 10 ; Middlesex, 1 ; Norfolk, 1 ; Northampton, 1 ; Northumberland, 19 ; Nottingham, 8 : Salop, 1 ; Stafford, 9 ; Surrey, 2 ; Sussex West, 1 ; Warwick, 3 : Yorks, North Riding, 5 ; West Riding, 38 ; Brecknock, 1 ; Glamorgan, 18 ; Monmouth, 15.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on July 3rd–4th was as follows :—Small-pox, 58 under treatment, 2 under observation ; scarlet fever, 1760 ; diphtheria, 1909 ; enteric fever, 16 ; measles, 520 ; [illegible] eral fever, 16 (plus 14 babies) [illegible] poliomyelitis, 1 ; " other dise [illegible] Hospital there were 18 babies (plus 15 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 31 (7) from measles, 5 (0) from scarlet fever, 24 (1) from whooping-cough, 29 (4) from diphtheria, 45 (10) from diarrhœa and enteritis under two years, and 31 (4) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London occurred at Newport (Mon.), and Cardiff. Of the 24 fatal cases of measles outside London, 5 were reported from Liverpool, 4 from Newcastle-on-Tyne, and 3 each from Birmingham and Middlesbrough. Of the 23 fatal cases of whooping-cough outside London 6 were reported from Birmingham and 3 from Liverpool. During the same week Glasgow reported 6 deaths from whooping-cough.

The number of stillbirths registered during the week was 333 in the great towns (corresponding to a rate of 50 per 1000 births), including 61 in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. A. R. Schofield to be Surg. Capt.

Surg. Lt. H. M. Devane to be Surg. Lt.-Comdr.

The following appointments are notified :—Surg. Comdrs. : E. B. Kenny to *President* for R.N. Recruiting Headquarters ; G. D. Walsh to *Pembroke* for R.M. Infirmary, Chatham ; A. G. Valpy French to *Pembroke* for R.N. Hospl., Chatham ; and J. G. Boal to *Berwick*. Surg. Lts. : W. V. Beach to *Wallace* ; A. L. McDonnell to *Vivid* for R.N. Hospl., Plymouth ; M. Clifford to *Renown* ; and J. M. Sloane to *Pembroke* for R.N. Hospl., Great Yarmouth. Surg. Lt.-Comdr. (D.) : D. Paterson to *Egmont* for R.N. Hospl., Malta. Surg. Lt. (D.) : D. Barker to *Victory* for R.M. Infirmary, Portsmouth, and to *Victory* for R.N. Barracks, Portsmouth.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. W. C. Macartney to be Surg. Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj. D. W. Bruce retires, receiving a gratuity.

W. A. Lethem (late Maj., R.A.M.C., Mila.) to be Maj.

Capt. D. P. H. Gardiner to be Maj.

Capt. A. U. Webster relinquishes his commn.

TERRITORIAL ARMY RESERVE.

Capt. J. C. Knox, from the Active List, to be Capt.

ROYAL AIR FORCE.

Squadron Leader R. H. Knowles to be Wing Comdr.

Flight Lt. C. A. E. I. Brownlee to be hon. Squadron Leader.

Flying Officer L. Freeman is promoted to the rank of Flight Lt.

Flight Lt. E. E. Isaac relinquishes his temporary commn. on completion of service and is permitted to retain his rank.

COLONIAL MEDICAL SERVICES.

Capt. R. Nixon, M.O., and Mr. H. H. B. Follit, M.O., Nyasaland, to be Sen. San. Offs. in the Tanganyika Territory. Mr. H. P. S. Gillette is appointed M.O., St. Lucia, Windward Islands.

"Audi alteram partem."

DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—As the university professorial and consulting element is so fully in evidence on the General Medical Council, it is fitting that the Direct Representatives of the profession should be general practitioners. With this I am absolutely in accord. At a meeting of the profession in my division (Kensington) it was resolved to put forward my name as a candidate for nomination at the coming election. I am, and have been, for the whole of my professional career a general practitioner pure and simple. I served for five years on the General Medical Council as a Direct Representative, and therefore am thoroughly conversant with its methods and procedure, so that if I were re-elected I could at once take my place in its deliberations without having to serve any apprenticeship. In the British Medical Association I have held every possible office, except that of Treasurer and Chairman of Council, having been chairman of my division, president of my branch, member of the General Council for 17 years, chairman of the Representative Body 1915–18, chairman of the Medico-Political Committee for seven years, president of a section at the general meeting in 1920, member, chairman, and vice-chairman of numerous special and "ad hoc" committees, and have also represented the Association on many outside bodies, in some cases for many years. During the whole of this time, both within the British Medical Association, and also very largely as a member of outside councils, I have done my utmost to further the honour and best interests of my profession. For these reasons I have allowed my name to go forward as a candidate, and I appeal to all members of the profession for their support. Should I be re-elected I should do my very best to carry out the duties of the post as I did when I was a member some years ago, when I never missed a single session or sitting of the Council.

I am, Sir, yours faithfully,

E. B. TURNER.

London, July 7th, 1928.

To the Editor of THE LANCET.

SIR,—Owing to the lamented death of Dr. J. A. Macdonald of Taunton, and to the resignation of Sir Robert Bolam (who has been appointed representative for the University of Durham), there will be, in October, an election of two Direct Representatives on the General Medical Council by the medical practitioners of England and Wales. It is understood that meetings of the profession will shortly be called in all parts of the country to consider nominations for such representatives.

The educational side of the Council's work is well cared for by the representatives of the various universities and licensing bodies. Many of these representatives, too, are thoroughly conversant with the special problems of consultant practice, being themselves actively working in that sphere.

Only two general practitioners at the moment have seats on the General Medical Council. The penal cases, which absorb so large a proportion of the Council's time, deal often with situations arising in the lives of general practitioners, as is only natural seeing that general practitioners constitute the bulk of the profession. The preparation of the medical student for ordinary family practice demands emphasis in the regulations laid down for his education, and for this the advice of general practitioners ought to be useful.

We are advised of a strong feeling that opportunity should be taken of this by-election to place upon the General Medical Council two Direct Representatives who have the closest possible touch with the problems own experience. I have written from the standpoint of my own experience, but have reason to believe that surgeons are victimized at least as frequently as are physicians! Obviously the practice is one that can hardly be suppressed by individual action. An analogous situation occurs sometimes, when the employers, the friends or the relatives of a panel patient ask the panel doctor to meet a specialist in consultation. The panel doctor does not desire to absent himself from the consultant's visit, but may spend time without hope of fee. He sometimes asks the consultant—who is paid by the employers—to "do something for" him in the matter. I have, in such a case, suggested that a fee should be paid directly in a complimentary way by the employers. But I was once asked by the panel doctor to add £2 2s. to my "account" for his sake!

I may perhaps say, in conclusion, that in my view the General Medical Council might well make a pronouncement to the effect that payments should always be made directly to the consultant and not through any intermediary, or that the amount of the fee should be stated by the consultant to the person responsible for the fee. It seems to me, however, that panel practitioners have a real grievance in not receiving the proper fee for being present at a consultation desired by the employers. This does not excuse an underhand method of obtaining a fee, though the existence of this real grievance has thus become apparent to me.

Let us hope that the publicity given to my experiences, which I know are shared by certain of my colleagues, will put an end to such practices.

I am, Sir, yours faithfully,

June 23rd, 1928. NEMO.

⁂ This letter reveals the existence of what is rightly styled an obnoxious practice. It is one that should receive immediate attention. Whether the General Medical Council would consider it any part of its duties or responsibilities to issue such a pronouncement as is sought, even in the form of a warning note, seems doubtful. The disciplinary powers of the Council would have to be set in action against those who disobeyed the pronouncement, or the Council would be stultified, and those powers can only be exercised if unimpeachable evidence were forthcoming. Publicity anyhow must act as a deterrent, opening the eyes of the public to a trick by which both they and a section of the medical profession may be victimised, although we hope that Nemo's experience is not a common one. If it is a fact that no provision can be made for the payment of panel doctors attending a consultation, the position should be altered.—ED. L.

"THE GREAT PROBLEM AND THE EVIDENCE FOR ITS SOLUTION."

To the Editor of THE LANCET.

SIR,—I was sorry to see in the honoured columns of THE LANCET a review which treated with contempt the recent book of Dr. Lindsay Johnson, "The Great Problem," in which he discusses spiritualism. Lindsay Johnson is a very highly qualified man and his views are shared by the vast majority of those who have actually investigated the subject. The opinion of those who have not is worth less. A century ago the medical profession stultified itself by its ridicule of mesmerism which it now uses as a powerful ally. It is sad to see it placing itself in the same false position towards spiritualism, for history will most certainly repeat itself.

As to the quality of the advertisements in psychic papers I agree with the reviewer that they might be improved, but is it reasonable to judge a vast subject not by the writings of a Lodge, a Crookes, a Wallace, a Richet, or a Flammarion, but by the advertisements in a few small papers?

I am, Sir, yours faithfully,

ARTHUR CONAN DOYLE, M.D. Edin.

Buckingham Palace Mansions, S.W.,
July 9th, 1928.

"IN AN INTERVIEW."

To the Editor of THE LANCET.

SIR,—Extracts from a paper by me on tuberculosis have been published by a newspaper and I should explain that no information of any sort was given by me, and that the extracts are based upon an advance copy of the *British Journal of Tuberculosis* obtained from the publishers. The account of the boxer was, I understand, obtained by the paper in the usual routine of news collecting; it certainly did not emanate from me. My real object in writing is to draw attention to the fact that another newspaper stated that I said "in an interview" that the treatment was still on its trial, or words to that effect. The "interview" actually consisted of asking me over the 'phone for an interview, and my reply that I could not possibly grant it, and that everything I had to say I had said in the *British Journal of Tuberculosis*.

I am, Sir, yours faithfully,

Manchester, July 10th, 1928. C. E. JENKINS.

THE TALE OF MEDICAL RESEARCH.

AN annotation published in our issue of June 30th under this heading has brought a communication from Mr. S. C. Turner, the Chairman of the Antivivisection (Battersea General) Hospital, protesting that statements made at the annual meeting of the Research Defence Society were misleading. Mr. Turner refers chiefly to the public announcement of Mr. Peart who, he says, remained surgeon to the hospital for four years after the situation was clear, while he had ceased to be honorary surgeon for two years when he made his announcement. Our words contained nothing to the contrary, and it is difficult to say why Mr. Peart should not be allowed to choose his own date for publicity, or to see in what way his period of silence has damaged the hospital.

UNIVERSITY OF ST. ANDREWS.—The Macewen prize in surgery has been awarded to Mr. Thomas Lawson McEwan, who is a graduate in medicine and in science of the University.

HOSPITALS AND THE MIDDLE CLASSES.—It is understood that the Pay Bed Committee of King Edward's Hospital Fund for London, appointed last year, will shortly issue its report on hospital accommodation for the professional and middle classes. The committee suffered a serious loss in the death of its chairman, Lord Hambleden, who, owing to his last illness, was unable to attend the deliberative meetings, though he had presided at the meetings when evidence was taken. The committee has devoted special attention to the question of voluntary insurance schemes.

BRITISH HUMANE ASSOCIATION'S LONDON CLINIC.—The officers of this clinic in Ranelagh-road, S.W., entertained several hundred medical visitors at a demonstration of therapeutic methods on the evening of July 10th. The institution was opened early this year by the British Humane Association; it succeeded the clinic in Tufton-street, and is one of the largest physiotherapeutic establishments in the world, its capacity being over a thousand patients a day. The ground floor houses offices and the saline and aromatic inhalation rooms, where patients with bronchial and pulmonary affections may breathe medicated air. On the first floor are the electrical and diathermy wards and a large tungsten-arc room. Almost the whole of the second floor is occupied by the mercury-vapour ward, and the whole clinic is elaborately equipped. The visitors saw the apparatus at work, and at a meeting over which Sir Bruce Bruce-Porter presided they listened to papers by Dr. Howard Humphris, who spoke on heliotherapy in general, by Dr. R. Deck, who gave an account of some unusual cases in tungsten-arc practice, and by Dr. Courtenay Mason, who explained the technique of inhalation treatment. The situation of the clinic is excellent, for it has a large poor population at its doors, and is accessible to south as well as to north London. Patients pay what they can afford, and it is stated that half of them make no payment. The clinic is maintained, as it was founded and equipped, at the expense of Mr. Campbell Johnston.

pernicious anæmia. Unfortunately, the nomenclature of diseases in the *Unani* system of medicine is rather defective, so that it is possible all the cases of anæmia thus treated may not have been of pernicious variety. Nevertheless, the fact that desiccated flesh including liver of a carnivorous crow has been highly recommended in the *Unani* system of medicine for anæmia makes it amply clear that the salutary effects of this treatment were well known to Orientals. To make further sure about this I referred to the book of therapeutics in the possession of a local Baluch *vaid* and found that there was in it first a description with signs of identification of this crow which is termed "Zagchah." Then the author proceeded to describe in detail its therapeutic qualities and recommended its desiccated flesh for regeneration of pure blood (*khalis khun*) in the system.

I may also state that I have seen *vaids* using similar things, but the Western science which has put therapeutics on a sound basis of reason does not permit even in thought the use of such drugs in that crude form. I am tempted to mention the following case by way of amplification. One patient had an attack of renal colic and the *vaid*, who was called in, had a goat slaughtered of which he removed the kidneys and made the patient swallow the same immediately, while they were still dribbling with blood. The patient not only obtained prompt relief but has not had an attack thereafter during the last eight years.

I am, Sir, yours faithfully,

P. V. KARAMCHANDANI, M.B., I.M.S.;

In charge Indian Military Hospital, Pishin,

June 11th, 1928. Baluchistan (India).

PERICARDIAL KNOCK.

To the Editor of THE LANCET.

SIR,—The communications on this subject from Dr. W. A. Lister and Dr. H. E. Symes-Thompson recall to my mind a case apparently unconnected with intrathoracic disease or injury. Some eight months ago a panel patient employed as manservant in London came to the south coast to convalesce from "neurasthenia." At the first consultation he gave a history of "shell-shock," and while recounting his then troubles he burst out crying. Five days later he called to apologise for having "made a fool of himself." He entered the consulting room in a very agitated state and said, "Do you hear my heart knocking, sir?" I was sitting at a distance of about five feet and the knock was distinctly audible for fully 20 seconds, and then stopped quite suddenly when the patient seemed more composed. Neither at that time nor at any later date have I found any physical abnormality. Two months later his mental condition having improved the patient found employment as a postman.

I wish now that I had used the stethoscope while the sound was audible, but at the time I was more amused than scientific. In this case, whose only abnormality was extreme nervousness accentuated by a desire to apologise for supposed lack of manliness, why should the left pulmonary artery be obstructed?—the cause suggested by Dr. Lister.

I am, Sir, yours faithfully,

Bexhill-on-Sea, July 9th, 1928. JOHN KERR.

To the Editor of THE LANCET.

SIR,—Dr. Symes-Thompson suggests that the peculiarly loud heart sounds in his case of empyema arose in the pulmonary artery, and are due to either tension or distortion of that artery. He also compares them to the sounds produced when estimating the blood pressure auscultatively. May I point out that there is no evidence whatever (1) that the artery was under increased tension or distorted; (2) that an artery distorted or under increased tension can produce a sound. He admits that as soon as the fluid was liberated from the chest the heart sounds disappeared; such an admission seems to prove that the fluid had a good deal to do with the production of the sounds. Such a fluid is easily moved by the moving heart, and moving fluid is particularly prone, especially when confined, to give rise to a sound.

My theory regarding the heart sounds is that they are due to the movements of the pericardial fluid which take place normally under a negative pressure of 6 to 8 cm. of water. If Dr. Symes-Thompson will half fill a rubber foot-warmer and shake it slowly from end to end he will hear noises resembling those due to his empyemic fluid. The comparison to the sounds heard when estimating blood pressure assumes that these sounds are produced by the vibrations in that artery, but a reference to my letter on the subject in your issue of May 12th last may tend to show that such an assumption is incorrect.

I am, Sir, yours faithfully,

Swansea, July 10th, 1928. G. ARBOUR STEPHENS.

BRITISH EMPIRE CANCER CAMPAIGN.

To the Editor of THE LANCET.

SIR,—I see that I am still stated to be Chairman of the Management Committee of the *Cancer Review* in the July number just published, and in the annual report of the British Empire Cancer Campaign. This is no longer the case as I resigned more than a month ago from this and the other Committees of the British Empire Cancer Campaign on which I had been serving. I shall therefore be obliged if any communications meant for me be addressed to 8, Queen-square, W.C.1.

I am, Sir, yours faithfully,

J. A. MURRAY,

Director, Imperial Cancer Research Fund.

London, July 6th, 1928.

AN OBNOXIOUS PRACTICE.

To the Editor of THE LANCET.

SIR,—It is right, I think, that attention should be called publicly to an obnoxious practice which is being rapidly extended in certain parts of London. I speak from facts within my own knowledge and with a complete sense of responsibility. I enclose my card for your information, but I do not sign my name, for some reasons that may be obvious, and for at least one that may not be obvious—namely, that I have no desire to appear more righteous than any of my neighbours. Still, I shall have no hesitation in giving my name if called upon, inasmuch as at present I feel intensely insulted at having been made repeatedly a party to a vulgar and dishonest trick. The insult is to my intelligence. I feel that I have been chosen as a dupe rather than as an accomplice. This is the sort of thing that happens. A physician is summoned in consultation, usually by telephone, on behalf of a practitioner whom he may or may not know. The message is to the effect that a fee of (say) £5 5*s.* will be paid to the physician. Or he is told that only £5 5*s.* can be paid, and he is asked to accept this. The consultation takes place, after which the practitioner leaves the room saying that he will see about the fee. He returns with the relatives for the usual interview and subsequently, perhaps outside the house, hands the consultant £5 5*s.*; but £2 2*s.* has been kept for himself, while the relatives believed that the consultant's fee was £7 7*s.* Sometimes the practitioner produces his own cheque at the consultation, for the agreed £5 5*s.*, receiving the £7 7*s.* from the family. There are several variants of the trick, all equally dishonourable, but not all equally clever, and two sources of weakness are obvious. One is that the relatives may insist on paying the consultant the full £7 7*s.*; the other is that the same consultant may be called in twice, the second time at the patient's own request, and with an honourable and straightforward practitioner in attendance. Discussion about the fee may lead to a reference to the previous fee, when the deception may be exposed. This has happened in my

Lead Poisoning Among Painters.

Lord **Henry Cavendish-Bentinck** asked the Home Secretary the number of cases of lead poisoning among painters for January, February, March, April and May, 1927, and for the same months of 1928; and what steps were taken to see that the regulations under the Lead Paints Act were being enforced.—Sir **W. Joynson-Hicks** replied: The number of cases reported for the first five months of 1927 was 33, and for the same period in 1928, 40. All cases of lead poisoning and complaints are fully investigated by the factory inspectors. It has always been recognised that on account of the special conditions under which the industry is carried on it would be necessary to rely to a large extent on the coöperation of the industry itself for securing general compliance with the regulations. With this object conferences were arranged with the employers' and operatives' associations, and I am glad to state that both sides have taken steps to impress on their members the importance of a strict observance of the regulations, and have promised to assist the department in every possible way.

Grants in Aid of Health Services.

Sir **Nicholas Grattan-Doyle** asked the Secretary to the Treasury whether he would state for the latest available year the amounts of the following grants to local authorities in England and Wales: percentage grants in aid of the following health services; tuberculosis, maternity, and child welfare; welfare of the blind; venereal disease; and mental deficiency.—Mr. **Chamberlain** replied: The following are the percentage grants in respect of the undermentioned health services:—

	£
Tuberculosis	1,640,098
Maternity and child welfare	767,082
Welfare of the blind	3,195
Venereal disease	302,158
Mental deficiency	505,642
	£3,218,175

The foregoing figures do not include the undermentioned amounts granted to voluntary associations:—

	£
Maternity and child welfare	197,119
Welfare of the blind	112,082
Venereal disease	152
Mental deficiency	8,422
	£317,775

Maternal Mortality Figures.

Mr. **Groves** asked the Minister of Health the maternal mortality figures for England and Wales for 1924 to 1927, and for the county borough of West Ham for the same periods.—Mr. **Chamberlain** replied: The following table shows the numbers of deaths classified as due to childbirth, and rates per 1000 live births, for England and Wales and for West Ham county borough, for the years 1924–27:—

Deaths due to childbirth—

England and Wales.			West Ham county borough.	
Year.	No.	Per 1000 live births.	No.	Per 1000 live births.
1924 ..	2847	3·90	12	1·66
1925 ..	2900	4·08	20	2·85
1926 ..	2860	4·12	13	1·94
1927* ..	2690	4·11	18	3·00

* Provisional figures.

Anthrax in Human Beings and in Foreign Imported Skins.

Dr. **Salter** asked the Home Secretary the number of cases of anthrax which had occurred in human beings and had been notified to his department during each of the last five years; the number of cases in which the disease proved fatal in each of those years; and the number of cases in which the infection was traced to its source or origin.—Sir **W. Joynson-Hicks** replied: The numbers in the years 1923 to 1927 were 50, 45, 48, 42, and 35 respectively, of which 8, 4, 10, 4, and 3 were fatal. In all except 7 of the cases the patient was found to have been in contact with materials likely to be infected with anthrax.

Dr. **Salter** asked the Home Secretary whether his department had investigated the serious outbreaks of anthrax at Newcastle, Warrington, and Bolton which had occurred this year; if so, what were the results of the inquiry; whether he had considered amending the regulations dealing with the treatment of hides and skins; whether he proposed to enforce arrangements for the efficient disinfection of foreign imported skins; and whether he intended to issue a welfare order in connexion with tanning and the leather industry generally.—Sir **William Joynson-Hicks** replied: Yes, Sir. Each of the cases—eight altogether—reported this year from the three places mentioned has been investigated. It was found that in every case except one the workman had been in contact with hides imported from China. The question of further precautions has for some time past been under discussion with the employers' and workers' associations, but it is agreed that the only measure likely to be effective would be disinfection. Investigations for this purpose were commenced some time ago by the United Tanners Federation, and are being actively pursued, but I regret that no satisfactory method has yet been worked out. The issue of a draft welfare order is also under consideration, and I hope that a decision will be reached very shortly.

MONDAY, JULY 9TH.

Report of Committee on Mental Deficiency.

Mr. **Harris** asked the President of the Board of Education when the Report of the Special Committee set up in 1923 to investigate various problems relating to mental deficiency will be ready; and whether it was proposed to issue the Report as a public document.—The Duchess of **Atholl** replied: My right hon. friend hopes that the Report will be available before the end of the year and that it will be published, but he cannot, of course, give an undertaking at this stage.

The Pace Case and Coroners' Powers.

Mr. **Purcell** asked the Prime Minister whether he would consider the matter of making adequate compensation to Mrs. Pace, who had been under police surveillance since Jan. 10th last, had been subjected to severe examination by Scotland Yard officers and a protracted coroner's inquiry, arrested on a charge of murder, kept in prison for a lengthy period, and compelled to undergo all the anguish and terrors on the capital charge, and who had now been released, no case having been proved against her; further, if the right hon. gentleman would institute a public inquiry into the position and powers of coroners, and whether, in the public interest, in view of the heavy expense involved in ensuring adequate legal defence, provision could not be made to guarantee to poor persons, particularly those implicated in charges involving life and death, the fullest and best legal and technical defence free from all cost.—Sir **Thomas Inskip** (Attorney-General) replied: This question raises three very important matters—firstly, the question of compensation to Mrs. Pace; secondly, the proposal to hold a public inquiry into the position of coroners; and, thirdly, a proposal to provide legal assistance for accused persons. In regard to the two last questions I am not now prepared to give any answer, except that these matters will receive due consideration by the proper authorities. With regard to the question of compensation to Mrs. Pace, she has been acquitted by a jury after a very careful and admittedly fair trial. There has been no departure from the ordinary course of the administration of justice. In these circumstances it must be undesirable, in the interests of justice generally, that any proposal for compensation in this case should be entertained.

Mr. **Morris** asked if the Attorney-General proposed to introduce an amendment of the law relating to coroners' juries, and limiting the power of such juries to inquiry into the cause of death only, leaving the verdict to be inquired into by the magisterial courts and the Assize Court.

Mr. **Macpherson** asked if the Attorney-General meant that the Government proposed to institute an inquiry into the question of the coroners' inquisition. If so, would he bear in mind that, in Scotland, there were no coroners and no coroners' inquisitions, and that the progress of justice was always safe and efficient

Sir T. **Inskip**: I did not say that the Government are contemplating an inquiry into the question of coroners' inquisitions. What I said was, that the question which has been submitted, at very short notice, will receive due consideration from the proper authorities, and everything would be borne in mind.

Mr. **Morris** said that quite apart from the facts of this particular case, there were two verdicts on record: that of the coroner's jury, finding the person guilty of murder, and the verdict reversing that at the Assize Court. That revealed an illogical state of the law. Was it not desirable, therefore, to amend the law, so as to limit the findings of the coroner's jury to the cause of death alone?

Sir T. **Inskip**: Whether that is desirable or not, it is not a proper subject of question and answer, without due opportunity for considering these important matters.

TUESDAY, JULY 10TH.

Hospitals and Motor Accidents.

Mr. **Hore-Belisha** asked the Minister of Transport whether, in view of the heavy and increasing burden imposed upon voluntary hospitals in the treatment and maintenance

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

REORGANISATION OF OFFICES (SCOTLAND) BILL.

ON Monday, July 9th, the Reorganisation of Offices (Scotland) Bill was considered in the House of Commons on Report and read the third time by 175 votes to 78. This is a measure which provides that the powers and duties of the Scottish Board of Health, the Board of Agriculture for Scotland, and the Prison Commissioners for Scotland shall cease to exist from the appointed day, and that their powers and duties shall be transferred to a Department of Health for Scotland, a Department of Agriculture for Scotland, and a Prisons Department for Scotland.

HOUSE OF LORDS;

MONDAY JULY 9TH.

Child Destruction Bill.

The Child Destruction Bill (formerly the Infanticide Bill) was considered in committee.

Lord DARLING formally moved that the amendments which had been made by the Select Committee to which the Bill had been referred should be agreed to. This was done, and the Bill passed through Committee.

Reading University Bill.

The Representation of the People (Reading University) Bill, a measure which gives the franchise to graduates of Reading University on the same lines as other universities, passed through Committee.

HOUSE OF COMMONS.

WEDNESDAY, JULY 4TH.

Rating of Hospitals.

Sir COOPER RAWSON asked the Minister of Health whether he had received any representations from local authorities or charitable organisations with regard to the effect of the operation of the Rating and Valuation Act of 1925 on hospitals and similar institutions; and whether he proposed to take any action in consequence.—Sir KINGSLEY WOOD replied: My right hon. friend has received communications on this subject from the British Hospitals Association and from the authorities of certain hospitals but not from local authorities. I can only refer to the reply which I gave on July 2nd.

Sir C. RAWSON asked if Sir Kingsley Wood was aware that the Sussex County Council had had their assessment raised from £100 to £1600, and if the assessment committees of the different localities were justified in making nominal assessments as they had done hitherto? If not, would the House have any opportunity of discussing the matter at an early date, as it affected so many hospitals all over the country?

Sir KINGSLEY WOOD said that if assessment committees were not acting properly and within the law there was a remedy by way of appeal.

Death of Two Factory Girls at Battersea.

Mr. WILLIAM THORNE asked the Home Secretary whether his attention had been called to the report of the Battersea coroner on the resumed inquest on two girls who died in hospital following illness they had contracted while employed at a scouring-powder works at Battersea; that the medical evidence showed that the cause of death was industrial silicosis and not tuberculosis, as at first diagnosed; that three girls and a boy employed at the same works had died since Jan. 25th, 1927; and if he would take any action in the matter in consequence of the dangerous nature of the work in handling the powder.—Sir W. JOYNSON-HICKS replied: Yes, Sir. A full report has been submitted to me by the Medical Inspector of Factories, who attended the inquest and investigated the circumstances. In the opinion of the medical inspectors these cases originated when the mixing and filling of the powder were done by hand. At the beginning of 1927, on the instructions of the district inspector of factories, mechanical methods of working were introduced. The plant since that date has been totally enclosed, and exhaust ventilation applied to all points where dust is liable to escape. I am advised that the present arrangements should prove effective, but they will continue to receive close attention.

Organised Draws for Hospital Funds.

Sir COOPER RAWSON asked the Home Secretary why a voluntarily organised draw on behalf of the funds of a Hove hospital was stopped by the Home Office while draws conducted on identical lines for other hospitals in Brighton and Hove had not been interfered with; and if an authoritative statement could be made for the guidance of those who organised these and similar functions on behalf of charities. —Sir W. JOYNSON-HICKS replied: The enforcement of the law relating to illegal lotteries is a matter for the local police and not for the Home Office. My attention was drawn to a public lottery at Hove in apparent contravention of the law, and I brought it to the notice of the local police. Had my attention been drawn to the other lotteries referred to, it would have been my duty to bring them also to the notice of the police. As I stated in reply to my hon. and gallant friend, the Member for Dulwich, on July 14th, public lotteries are definitely illegal, and the law does not discriminate between those promoted in aid of charity and other public lotteries. I have no authority to decide what is or is not a public lottery, but it is always open to the promoters of charities to consult the local police on the question whether any proposed lottery appears to contravene the law.

Sir C. RAWSON asked whether, as this particular question would deprive the hospitals in the constituency of Brighton and Hove of some £15,000 a year, the Home Secretary would persuade the Government to introduce legislation to remove some of the anomalies and stupidities of the existing law in regard to gaming.

Sir W. JOYNSON-HICKS said that he had already issued two memoranda on the subject of gaming. The law as regarded lotteries, however, was definite, and did not permit of any action by his department.

Sir C. RAWSON: Will the right hon. gentleman suggest an alteration of the law?

No reply was given to the question.

THURSDAY, JULY 5TH.

Provision for Mentally and Physically Defective Children.

Mr. HARRIS asked the President of the Board of Education how many local education authorities had provided no accommodation up to the present for mentally defective and physically defective children; and were there any authorities without accommodation who were making provision during the current educational triennium.—The Duchess of ATHOLL (Parliamentary Secretary to the Board of Education) replied: According to the information in the possession of my department, there are 240 local education authorities who have provided no special schools of their own for mentally defective children, and 257 who have provided no special schools of their own for physically defective children; but 131 of the former authorities and 221 of the latter send children of these types to special schools provided by other authorities or by voluntary managers, and some 200 authorities make provision for the orthopædic treatment of crippled children. In addition, about 50 authorities have arranged for the supervision of mentally defective children in their areas. As to the second part of the question, the Board already have before them proposals for the provision of five new schools for mentally defective children, and 28 new schools for physically defective children.

Insurance Patients and Vitamin Preparations.

Miss WILKINSON asked the Minister of Health whether he was aware that certain insurance committees had decided that insurance practitioners must not order for their patients vitamin preparations on the ground that they were not drugs but food, while other committees allowed doctors to prescribe vitamin preparations; and whether he could ensure that insurance patients were not deprived of such necessary products recognised by modern medical practice.—Mr. CHAMBERLAIN replied: The question whether any particular preparation can be regarded as a medicine within the meaning of the National Health Insurance Acts is one to be determined by the local insurance committee, and would only come before me formally on an appeal from their decision. I am, however, aware that there is a divergence of practice between committees on the point, and I am proposing to issue a statement for the purpose of assisting insurance practitioners and committees in their consideration of it in future.

Poor-law Medical Officers and Extra Remuneration.

Captain FAIRFAX asked the Minister of Health if he had received an appeal from the Norfolk vagrancy committee for assistance in providing extra remuneration for medical officers of poor-law institutions now called upon, by order of the Ministry, to examine all casuals for small-pox; and, in view of the fact that this work was outside the duties ordinarily performed by these doctors, whether he would undertake to defray all or part of the additional fees involved. —Mr. CHAMBERLAIN replied: The answer to the first part of my hon. and gallant friend's question is in the affirmative, and to the second part in the negative. There are no funds at my disposal out of which such a contribution as is suggested could be paid.

Royal College of Surgeons of England.—The annual election of Fellows into the Council was held on July 5th. There were 12 candidates for four vacancies, and the following were elected: Prof. R. E. Kelly (Liverpool), 446 votes; Mr. F. J. Steward (London), 409 votes; Mr. R. G. Hogarth (Nottingham), 407 votes; and Prof. L. P. Gamgee (Birmingham), 399 votes. The number of voting papers received was 1169.

University of London: *University College.*—Dr. John Kirk has been appointed demonstrator in the department of anatomy and embryology.

University of Birmingham.—At a Congregation held on June 30th the degree of M.D. was conferred on I. de B. Daly, J. F. Brailsford, and F. W. M. Lamb. The degrees of M.B. and Ch.B., and B.D.S. were conferred on the candidates whose names were given on p. 44 of our last issue as having passed the requisite examinations.—The Queen's scholarships for the third, fourth, and final year were awarded to K. S. Williams, W. C. Smallwood, and G. H. Knight respectively; the Ingleby scholarships to F. R. Roberts and A. B. Taylor, the Arthur Foxwell Memorial medal to A. B. Taylor, the Peter Thompson prize in anatomy to James Hardman, and the Samson Gamgee Memorial medal for surgery to G. H. Knight.

Dr. Frank Gower Gardner, of Oxford, Captain R.A.M.C. (T.) (ret.), has been elected County Director of the British Red Cross Society for Oxfordshire in place of Colonel Stanier Waller, resigned.

College of Nursing.—The College's petition for a Royal Charter, placed before the Privy Council by Sir Cooper Perry, has been successful.

It is announced that Dr. F. d'Herelle, who has recently been working in India on the treatment of cholera by bacteriophage, has been appointed professor of bacteriology at the Yale School of Medicine, Connecticut, U.S.A.

British Institute of Philosophical Studies.—The annual general meeting of this institute will be held at the Royal Society of Arts, 18, John-street, Adelphi, London, W.C., on Monday, July 16th, at 5.30 P.M. The Earl of Balfour will preside and deliver a short address. Other addresses will be given by Sir Robert Horne, Sir Martin Conway, and the chairman of the institute, Prof. L. T. Hobhouse.

International Congress of Physiology.—The thirteenth International Physiological Congress will meet at the Medical School of Harvard University, Boston, Massachusetts, from August 19th to 23rd, 1929. The Federation of American Societies for Experimental Biology will serve as hosts to the Congress, and Prof. William H. Howell, of Johns Hopkins University, will be the president. The arrangements for the Congress are in charge of Prof. Walter B. Cannon, of the Harvard Medical School, who is chairman of the Congress Bureau, and Prof. Edwin J. Cohn and Alfred C. Redfield, who are the secretaries.

Post-Graduate Courses in Paris.—Holiday courses will be held at the Clinique Médical de l'Hôtel-Dieu from Sept. 10th to 22nd, and from Oct. 1st to 13th, under the direction of Prof. P. Carnot and Prof. M. Villaret. The subjects will be, respectively, Recent Views of Diabetes and Hepatic Diseases, and Recent Views of Digestive Disorders. The interval will be spent in a visit to Vichy. A course on pediatrics will be held at the Clinique Médicale des Enfants, 149 rue de Sèvres, from July 26th to August 11th, under the direction of Prof. Nobécourt. Those wishing to attend any of these courses should communicate with the Secretary of the Faculty of Medicine (Guichet No. 4) of the University of Paris.

First International Congress of Oto-Laryngology.—This Congress takes place at Copenhagen on July 30th and 31st and August 1st, 1928, and intending visitors should send in their subscription without delay. This has been fixed at 30 Danish kroner per head, with the addition of 15 Danish kroner for every lady in the party, and payment can be made with an English cheque if this be dispatched at once to the hon. treasurer, Dr. Jorgen Moller, Vestre Boulevard 13, Copenhagen. On receipt of the subscription a programme will be dispatched from Denmark giving a list of the festivities and excursions in connexion with the Congress and a form on which should be entered an application for the tickets desired. The application form should be returned without delay to the Secretary-General, Dr. N. Rh. Blegvad, Nytorv 3, Copenhagen. Those who have not already secured hotel accommodation should apply at once to Bennett's Tourist Office, 45, Raadhuspladsen, Copenhagen V., while particulars and tickets for the journey can be obtained from Messrs. Bennett, 66, Haymarket, S.W. 1, and Messrs. Thos. Cook and Son, Berkeley-street, W. 1.

Prof. Share Jones, Professor of Veterinary Science at the University of Liverpool, has been appointed President of the Royal College of Veterinary Science.

Sanatorium's Change of Name.—Highfield Sanatorium, in Edge Lane Drive, Liverpool, will in future be known as Broadgreen Sanatorium.

Osteolysis in the Mouth.—We are informed that a series of photomicrographs by Dr. Arthur Hopewell-Smith, illustrative of the process of osteolysis as it occurs in the oral cavity, has been added to the annual exhibition of the Museum of the Royal College of Surgeons, Lincoln's Inn-fields, London, W.C. The exhibition will remain open until July 28th.

Extension of Jenny Lind Hospital.—Mrs. Raymond Maude, daughter of the foundress, has laid the foundation-stone of a new out-patient and special department block of this Norwich hospital for children. The extension, which is being partially paid for by a grant from the Norwich Joint Hospitals and War Memorial Fund, includes accommodation for the electrical, X ray, and massage departments. Mrs. Maude also opened Pym House, a nurses' hostel, formed by throwing two houses into one, which has been provided from a bequest by the late Mrs. Radford Pym.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, July 16th, to Saturday, July 21st.—Royal Westminster Ophthalmic Hospital, Broad-street, Holborn, W.C. Special afternoon demonstration in Ophthalmology at 3 P.M. on Thurs., by Mr. Caddy. No fee.—Prince of Wales's Hospital, Tottenham, N. Second week of course in medicine, surgery, and the allied specialties. Daily 10.30 to 5.30 P.M. Further information from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

Monday, July 16th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

Tuesday.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

Wednesday.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

Thursday.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

Friday.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

Appointments.

Don, C. S. D., M.B., Ch.B. Aberd., has been appointed Honorary Assistant Physician, Salford Royal Hospital.

Forrest, A. W., M.D., Ch.B. Edin., D.P.H., Medical Officer of Health and School Medical Officer for Leyton.

Russell, G. J. C., M.B., Ch.B. Manch., D.P.H., Assistant Medical Officer for Maternity and Child Welfare, Leeds Corporation.

Vacancies.

of motor accident cases, he would consider introducing a Bill rendering insurance compulsory upon all motor drivers and the cost of treatment and maintenance of motor accident cases admitted to voluntary hospitals being made a first charge upon the insurance money.

Sir JOHN MARRIOTT asked the Minister of Transport whether his attention had been drawn to the increasing burden imposed upon voluntary hospitals for the treatment of cases arising from motor accidents; and whether he would introduce legislation to make the insurance of all drivers of motor-cars compulsory and to make the cost of the treatment of motor accident cases a first charge upon the insurance payment.—Colonel W. ASHLEY replied: I have received a copy of the resolution to which the hon. Member refers. The compulsory insurance of all motor vehicles would involve great difficulties, but even if they could be overcome I do not think that it would be practicable to make the cost of treatment and maintenance in voluntary hospitals a first charge on the insurance monies. In order to bring the matter within the scope of a policy of insurance, it would be necessary, in the first place, that the hospital should have an enforceable claim against the patient, and in the second that the patient's injury, if he was a third party, should have been due to negligence on the part of the driver of the vehicle.

Disinfection of Casuals' Clothing.

Mr. SHEPHERD asked the Minister of Health whether, in view of the fact that the method most commonly used for the disinfection of the clothing of casuals rapidly destroyed the material, he would issue regulations to boards of guardians whereby disinfection would not destroy such clothing.—Sir KINGSLEY WOOD replied: My right hon. friend is advised that articles of clothing can be repeatedly disinfected without being damaged, though after a time the process may tend to deteriorate the clothing. He is afraid no regulations which he can issue will alter the position in this regard.

Medical News.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful:—

M.D.

C. B. Bamford, C. A. Birch, J. D. Craig, M. M. Datnow, R. Y. Dawbarn, S. B. Hall, and Nellie Wall-Mesham.

CH.M.

P. R. Hawe and P. Malpas.

M.B. AND CH.B. WITH HONOURS.

Class I.—T. B. Davie,[1,2,3] J. H. Follows,[1,3] and E. W. Jones.[1,2]
Class II.—E. T. Bates,[1] T. L. Dowell,[1] and M. Silverstone.[3]

FINAL EXAMINATION FOR M.B. AND CH.B.

Part III. (Old Regulations).—S. W. Adler, S. Canter, Gladys A. Coventry, Ariel R. S. Deacon, H. R. Dugdale, Ruth M. Fennell, Agnes G. Gillespie, R. G. Gornall, J. J. Graham, G. T. Harris, K. Jilani, Mary G. Jones, W. E. J. Jones, T. Lasker, N. R. Lawrie, H. Leiper, J. R. Mitchell, T. C. Newman, Winifred O'Callaghan, J. Pasvolsky, H. Paterson, H. W. Smith, G. G. Warburton, and A. L. Williams.

[1] Distinction in Medicine. [2] Distinction in Surgery. [3] Distinction in Obstetrics and Gynæcology.

M.B. AND CH.B.

Part A (New Regulations).—A. H. Barzilay, M. J. Bennett-Jones,[7] L. Findlay,[4,5,6,7] A. T. Halton, J. C. Hill, T. N. A. Jeffcoate,[5,7] D. A. Jones, J. Libman,[4,5,6,7] G. A. C. Lynch, J. A. Martinez,[7] H. J. Partington,[4,7] C. L. Pratt, C. K. Sconce, E. B. Whittingham, and J. P. Woodward.[7]
Part I. (Old Regulations).—A. L. Beresford and F. J. H. Crawford.
Part II. (Old Regulations).—J. D. Bright-Richards and Florence M. E. Davies.

[4] Distinction in Special Pathology. [5] Distinction in Forensic Medicine. [6] Distinction in Public Health. [7] Distinction in Pharmacology and General Therapeutics.

D.P.H.

W. T. Donovan, S. C. Gawne, Thirza Redman, Mary H. Wild, and Grace H. Wood.

D.T.M.

J. D. Bilimoria, W. L. Blakemore, K. V. R. Choudari, K. K. Dhar, W. E. Holmes, W. S. Maclay, A. H. Morley, I. Sanderson, and S. Sivalingam.

UNIVERSITY OF MANCHESTER.—At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B. AND CH.B.

G. L. Brown,* Doris Bernard, E. H. Brooks, Mary G. Davies, Ralph Edmundson, Alexandra W. Groves, G. B. Hardman, Simon Kelly, Morris Levine, J. A. Longworth, Stanley Nowell, S. L. Rowley, R. F. Sheppard, Henry Tickle, and J. F. Wilkinson.

* With second-class honours and distinction in obstetrics.

The following have satisfied the examiners in the undermentioned subjects:—

Forensic Medicine.—J. S. Miller.
Medicine.—I. M. Hughes.
Hygiene, &
Obstetrics Alice M. Butterworth,
M. A. C Evelyn I. M. Sheppard,
Raymond Whitehead, and Frederick Wraith.
Forensic Medicine, Hygiene,
Allan, H. S. Bagshaw, I
Edith M. Booth, B. R.
Brown, Bessie H. E. Cac
W. W. Fox, J. N. Greenv
F. N. Marshall, A. B.
O'Loughlin, G. E. Plowright, B. P. Robinson, Donal Sheehan, C. F. Stott, Nellie Wilson, and L. C. Wright.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Richard Handley, J. E. Howie, W. H. Shepley, and Harry Stafford.
Part I.—Nicolas Gebbie.

DIPLOMA IN BACTERIOLOGY.

A. W. Laing.

DIPLOMA IN PUBLIC HEALTH.

Part I.—Andrew Anderson, Frank Appleton, Helen G. M. Bennett, Arnold Brown, J. J. O'Reilly, Jean M. Orkney, Mary I. Prentice, Kathleen Sheehan, and P. H. J. Turton.

FINAL EXAMINATION FOR B.D.S.

S. R. Medd and F. W. Williams.

FINAL EXAMINATION FOR DIPLOMA IN DENTISTRY.

Mary M. Brandwood, Bernard Cooke, D. L. Parkes, J. N. Peacock, L. D. Smith, W. G. Taylor, and G. B. Warburton.

UNIVERSITY OF ABERDEEN.—At a graduation ceremony held on July 3rd the following degrees were conferred:—

Hon. LL.D.—John Alexander MacWilliam, F.R.S., Emeritus Professor of Physiology in the University.
M.D.—Wilfrid Marshall,* Mathilda F. Menzies,† C. S. D. Don,‡ I. G. Innes,‡ Edward James,‡ Beatrix B. Law,‡ Roderick Mackay,‡ Katherine C. Spence‡, Walter Graham, Robina Inkster, Alexander Johnstone, Moore Taylor, and W. L. Yell.

*Awarded highest honours for thesis. †Awarded honours for thesis. ‡Awarded commendation for thesis.

M.B. and Ch.B.—B. S. Cran * and J. A. Gordon * (with second-class honours); Henry Aitken, R. D. Bruce, D. D. Callaghan, S. E. N. Chinniah, Andrew Dickson, William Fettes, J. S. Firth, H. M. Gray, Norman Jolly, J. S. Lawrie, A. W. R. MacKenzie,* R. J. Mackenzie, M. M. Milne, J. L. Nicol, J. M. Paterson, C. S. Philip, Margaret F. Reid, J. S. Robertson, W. M. Smith, Andrew Stephen, C. H. Strachan, Alfred Wilkie,* G. A. Wilson, and J. A. D. Wyness.

* Completed Final Medical Professional Examination with distinction.

B.Sc.—Wilfrid Marshall, M.D.
D.P.H.—J. L. Gammie (with credit), J. R. W. Hay, and A. J. W. Wilkins.

UNIVERSITY OF DUBLIN.—At a meeting of the Senate on June 30th the degree of M.D. was conferred on C. R. Boland, W. S. Dickson, and H. J. Hugo. At recent examinations the following candidates have been successful:—

FINAL EXAMINATION FOR M.B., B.CH. AND B.A.O.

Part I., Therapeutics, Pathology, &c.—*Eva E. Moore, F. O. Pilkington, J. T. Robinson, R. T. O'Shea, Dora G. Bradley, E. S. Tweedy, Frances E. Wilson, R. E. Hemphill, W. A. Robinson, Kathleen A. Wilson, and N. S. Klass.
Part II., Medicine.—C. P. Martin, E. K. Malone, Julius Sayers, D. M. Brink, I. F. Ratthaus, R. H. Bland, Julius Horwich, Nathaniel Burstein, R. I. G. Reid, and J. M. M'Elligott.
Surgery.—W. J. E. Jessop, C. P. Martin, G. W. F. Pratt, I. W. Pigott, H. S. Smithwick, R. F. W. K. Allen, R. H. Bland, E. S. Adderley, Nora A. Stack, D. S. P. Wilson, F. O. W. A. Mahon-Daly, H. R. F. Tweedy, D. M. Brink, E. C. Hicks, Mollie Finegan, A. J. Burden, H. J. Robinson, Marie M. E. Lea-Wilson, and L. R. H. Keatinge.
Midwifery.—*G. C. Dockeray, A. G. Thompson, M. H. Fridjhon, M. E. Kirwan, L. L. Griffiths, W. R. Johnston, Josephine M. Enright, Anna M. E. M'Cabe, J. E. C. Cherry, N. H. Lindsay, and W. A. Y. Knight.

DIPLOMA IN PUBLIC HEALTH.

Part I.—C. R. Nunan, R. A. Q. O'Meara, *Sarah Walsh, Michael Casey, W. A. Dickson, and Mary E. Ryan.
Part II.—C. R. Nunan, P. H. Lemass, Kathleen M. Ball, and Alice E. S. Delany.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS.

Eva Ho Tung.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Parts I. and II.—K. K. Drury.

* Passed on high marks.

CONGRESS OF SURGERY IN FRANCE.—The thirty-seventh French Surgical Congress will meet at Paris from Oct. 8th to 13th. Subjects on the agenda are the present status of spinal anæsthesia, the remote results of surgical treatment of duodenal ulcer, and the remote results of cranial trepanning for injuries.

Royal College of Surgeons of England.—The annual election of Fellows into the Council was held on July 5th. There were 12 candidates for four vacancies, and the following were elected: Prof. R. E. Kelly (Liverpool), 446 votes; Mr. F. J. Steward (London), 409 votes; Mr. R. G. Hogarth (Nottingham), 407 votes; and Prof. L. P. Gamgee (Birmingham), 399 votes. The number of voting papers received was 1169.

University of London: *University College.*—Dr. John Kirk has been appointed demonstrator in the department of anatomy and embryology.

University of Birmingham.—At a Congregation held on June 30th the degree of M.D. was conferred on I. de B. Daly, J. F. Brailsford, and F. W. M. Lamb. The degrees of M.B. and Ch.B., and B.D.S. were conferred on the candidates whose names were given on p. 44 of our last issue as having passed the requisite examinations.—The Queen's scholarships for the third, fourth, and final year were awarded to K. S. Williams, W. C. Smallwood, and G. H. Knight respectively; the Ingleby scholarships to F. R. Roberts and A. B. Taylor, the Arthur Foxwell Memorial medal to A. B. Taylor, the Peter Thompson prize in anatomy to James Hardman, and the Samson Gamgee Memorial medal for surgery to G. H. Knight.

Dr. Frank Gower Gardner, of Oxford, Captain R.A.M.C. (T.) (ret.), has been elected County Director of the British Red Cross Society for Oxfordshire in place of Colonel Stanier Waller, resigned.

College of Nursing.—The College's petition for a Royal Charter, placed before the Privy Council by Sir Cooper Perry, has been successful.

It is announced that Dr. F. d'Herelle, who has recently been working in India on the treatment of cholera by bacteriophage, has been appointed professor of bacteriology at the Yale School of Medicine, Connecticut, U.S.A.

British Institute of Philosophical Studies.—The annual general meeting of this institute will be held at the Royal Society of Arts, 18, John-street, Adelphi, London, W.C., on Monday, July 16th, at 5.30 P.M. The Earl of Balfour will preside and deliver a short address. Other addresses will be given by Sir Robert Horne, Sir Martin Conway, and the chairman of the institute, Prof. L. T. Hobhouse.

International Congress of Physiology.—The thirteenth International Physiological Congress will meet at the Medical School of Harvard University, Boston, Massachusetts, from August 19th to 23rd, 1929. The Federation of American Societies for Experimental Biology will serve as hosts to the Congress, and Prof. William H. Howell, of Johns Hopkins University, will be the president. The arrangements for the Congress are in charge of Prof. Walter B. Cannon, of the Harvard Medical School, who is chairman of the Congress Bureau, and Prof. Edwin J. Cohn and Alfred C. Redfield, who are the secretaries.

Post-Graduate Courses in Paris.—Holiday courses will be held at the Clinique Médical de l'Hôtel-Dieu from Sept. 10th to 22nd, and from Oct. 1st to 13th, under the direction of Prof. P. Carnot and Prof. M. Villaret. The subjects will be, respectively, Recent Views of Diabetes and Hepatic Diseases, and Recent Views of Digestive Disorders. The interval will be spent in a visit to Vichy. A course on pædiatrics will be held at the Clinique Médicale des Enfants, 149 rue de Sèvres, from July 26th to August 11th, under the direction of Prof. Nobécourt. Those wishing to attend any of these courses should communicate with the Secretary of the Faculty of Medicine (Guichet No. 4) of the University of Paris.

First International Congress of Oto-Laryngology.—This Congress takes place at Copenhagen on July 30th and 31st and August 1st, 1928, and intending visitors should send in their subscription without delay. This has been fixed at 30 Danish kroner per head, with the addition of 15 Danish kroner for every lady in the party, and payment can be made with an English cheque if this be dispatched at once to the hon. treasurer, Dr. Jorgen Moller, Vestre Boulevard 13, Copenhagen. On receipt of the subscription a programme will be dispatched from Denmark giving a list of the festivities and excursions in connexion with the Congress and a form on which should be entered an application for the tickets desired. The application form should be returned without delay to the Secretary-General, Dr. N. Rh. Blegvad, Nytorv 3, Copenhagen. Those who have not already secured hotel accommodation should apply at once to Bennett's Tourist Office, 45, Raadhuspladsen, Copenhagen V., while particulars and tickets for the journey can be obtained from Messrs. Bennett, 66, Haymarket, S.W. 1, and Messrs. Thos. Cook and Son, Berkeley-street, W. 1.

Prof. Share Jones, Professor of Veterinary Science at the University of Liverpool, has been appointed President of the Royal College of Veterinary Science.

Sanatorium's Change of Name.—Highfield Sanatorium, in Edge Lane Drive, Liverpool, will in future be known as Broadgreen Sanatorium.

Osteolysis in the Mouth.—We are informed that a series of photomicrographs by Dr. Arthur Hopewell-Smith, illustrative of the process of osteolysis as it occurs in the oral cavity, has been added to the annual exhibition of the Museum of the Royal College of Surgeons, Lincoln's Inn-fields, London, W.C. The exhibition will remain open until July 28th.

Extension of Jenny Lind Hospital.—Mrs. Raymond Maude, daughter of the foundress, has laid the foundation-stone of a new out-patient and special department block of this Norwich hospital for children. The extension, which is being partially paid for by a grant from the Norwich Joint Hospitals and War Memorial Fund, includes accommodation for the electrical, X ray, and massage departments. Mrs. Maude also opened Pym House, a nurses' hostel, formed by throwing two houses into one, which has been provided from a bequest by the late Mrs. Radford Pym.

Marseilles, Queen Alexandra Memorial Hospital.—Res. M.O. At rate of £150.

Middlesex Hospital and Medical School.—Surgical Registrarship. At rate of £300.

Newark Hospital and Dispensary.—Res. H.S. At rate of £150.

Norwich, Norfolk and Norwich Hospital.—H.S. £120.

Nottingham, City Mental Hospital.—Jun. Asst. M.O. £350.

Nottingham General Hospital.—Res. Cas. O. At rate of £200.

Nottinghamshire County Council and Mansfield Woodhouse Urban District Council.—Joint M.O. £700.

Portsmouth, Royal Portsmouth Hospital.—Sen. H.S., also Cas. O. At rate of £200 and £100 respectively.

Preston and County of Lancaster Royal Infirmary.—H.P. and H.S. £190 and £150 respectively.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal Army Medical Corps.—Commissions.

St. John's Hospital, Lewisham, S.E.—Res. H.O. Also Res. Cas. O. Each at rate of £100.

St. Luke's Hospital, Chelsea, S.W.—Consulting Physician. 100 guineas.

Society of Apothecaries of London.—Examiner in Midwifery.

Staffordshire, Lechfield County Laboratory.—Bacteriologist. 10 gns per week.

Taunton, Taunton and Somerset Hospital.—Sen. and Jun. House M.O.'s. At rate of £150 and £100 respectively.

West London Hospital, Hammersmith-road, W.—Res. Asst. Surg. £200.

Woolwich and District War Memorial Hospital, Shooters' Hill, S.E.—Sen. H.S., also H.P. Each at £125.

Worcester County and City Mental Hospital, Powick, near Worcester.—Jun. Asst. M.O. £300.

The Chief Inspector of Factories announces the following vacancies for Certifying Factory Surgeons: Falkland (Fifeshire), Bourton (Dorsetshire), Rothwell (Northamptonshire), Llanfairfechan (Carnarvonshire), Wirksworth (Derbyshire), and Crook (Co. Durham).

Notice is given of a vacancy for a Medical Referee under the Workmen's Compensation Act for Edinburgh City and Linlithgow County (Sheriffdom of the Lothians and Peebles). Applications should reach the Private Secretary, Scottish Office, Whitehall, London, S.W., not later than July 28th.

Births, Marriages, and Deaths.

BIRTHS.

BATEY.—On July 4th, at Beaufort House, Ealing, W., the wife of Maurice Batey, L.D.S. R.C.S. Eng., of a son.

DIX.—On July 6th, 1928, at 11, Alexandra Park-road, N. 10, to Nan, the wife of Victor Dix, F.R.C.S.—a daughter.

HERN.—On July 2nd, at Lexham-gardens, W., the wife of Dr. J. R. B. Hern, of a daughter.

KINGDON.—On July 4th, the wife of A. T. L. Kingdon, M.R.C.S., L.R.C.P., of South-street, Leominster, of a daughter.

DEATHS.

BOWKER.—On July 6th, at North Parade, Bath, George Edward Bowker, M.D. Edin.

PARSONS.—On July 2nd, at Bournemouth, John Inglis Parsons, M.D., M.R.C.P., M.R.C.S., aged 71.

PRITCHARD.—On July 6th, W. Clowes Pritchard, M.R.C.S., L.R.C.P., of Hastings.

STONEY.—On July 5th, at Abbeyleix, Ireland, Hugh Baker Stoney, M.B.

WIGGINS.—On July 3rd, suddenly, Charles Wiggins, M.R.C.S., L.R.C.P., of Argyll, Fortis Green, East Finchley.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET,"

VOL. I., 1928.

THE Index and Title-page to Vol. I., 1928, which was completed with the issue of June 30th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

HOSPITAL LAW.

LIABILITY OF HOSPITALS AND THEIR PROFESSIONAL STAFFS.

BY CAPTAIN J. E. STONE, M.C., F.S.A.A.,

HON. SECRETARY, INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS.

II.*—LIABILITY OF SUBORDINATES.

PHYSICIANS and surgeons of a hospital are not necessarily liable for injury caused by the carelessness of their subordinates in carrying out the treatment ordered by them, unless it can be shown that the matter was one which ought not to have been left to a subordinate, or that they had *themselves neglected some precautions* which ought to have been taken, or had superintended or been present at the carrying out of the treatment. Thus, where a patient was severely scalded by reason of the negligence of a nurse in administering a hot bath ordered by the surgeon, it was held that the surgeon was not liable. It was proved to be the usual hospital practice to leave it to the nurses to see to the baths. *The decision, however, does not deal with* the question whether or not the hospital itself was liable for the negligence of the nurse.

A sister or nurse may equally be liable for negligence in carrying *out the duties entrusted* to her. In the case above mentioned, the action which failed against the surgeon would probably have succeeded against the nurse. Members of the nursing staff may also incur liability if they exceed the duties assigned to them; their functions are subordinate to those of the physician and surgeon, and any attempt by nurses to usurp the place of a qualified *medical officer might place them in peril.*

Where the injury to a patient is the immediate result of intervening negligence on the part of the patient himself, or where the patient by his own carelessness directly contributes to it, the patient's contributory negligence is a good defence to an action. Where, however, damages are obtainable, and the patient dies, they may be recovered for the *benefit of his or her wife, husband, parent,* or child.

Criminal Negligence.

There is a distinction between the negligence which gives right to damages in a civil action and the negligence sufficient to support a conviction in a criminal case. The distinction, however, is not clear, and it is perhaps rather a question of degree. Gross negligence is of two kinds, as for example: (1) when a physician deliberately neglects his patients; and (2) when a person without skill in his profession *ignorantly* and rashly uses dangerous medicine. Criminal liability is incurred by a competent person for death occasioned by gross want of care; as, for example, by insufficient attention to a woman after her confinement. Malpractice, which generally means an unprofessional treatment of disease, pregnancy, or body injury, either from gross carelessness or ignorance, or with *criminal* intent, would *certainly extend* to the performance of operations for mere curiosity or experiment, which is a criminal offence. *Mala praxis* is a great misdemeanour and offence *at common* law (whether *it be for curiosity* or experiment, or by neglect), because it breaks the trust which the party has placed in the physician. Doctors and nurses may *therefore* incur personal liability: (*a*) to an action for damages for incompetence and negligence; (*b*) to criminal proceedings for malpractice and criminal negligence.

Relationship of Professional Staff to Hospital.

As liability for criminal acts cannot extend beyond the persons themselves, it is only in respect of *their* liability to a *civil action that* the question of the consequent liability of the hospital whom they represent need be considered. It is clear that the foundation of any such liability *must* rest upon *the law of agency*. The general doctrine of law is that although the principal is not ordinarily liable (for he sometimes is) in a criminal suit for the acts or misdeeds of his agent, unless indeed he has authorised or coöperated in those acts, &c., yet he is held liable to third persons in a civil suit for the frauds, deceits [illegible]representations, negligences, and *other* [illegible]nces and omissions of duty of his agent in the course of his employment, although the principal did not authorise, justify, participate in, nor indeed, know of *such misconduct*, or *even if he forbade the acts* or disapproved of them. In all such cases the rule applies *respondeat superior*, and it is founded upon public policy and convenience, for in no other way could there be any safety to third persons in their dealings, either directly with the principal or indirectly with him through the instrumentality of agents. In every such case the principal holds out his agent as competent and fit to be trusted, and thereby in effect he warrants his fidelity and good conduct in all matters coming within the scope of his agency.

---

* The previous article of this series appeared in THE LANCET of April 28th, p. 895.

Who are servants of a hospital?—The principle is well established that a master is liable for the negligence of his servant who is acting in the course of his employment. This principle of liability applies to hospitals in the same way that it applies to individuals. The term "servant" has in law a much more restricted meaning than that which is popularly attributed to it. A servant has been defined as—"Any person employed by another to do work for him on the terms that he, the servant, is to be *subject to the control and direction of his employer* in respect of the *manner* in which his work is to be done." A servant as thus defined must be distinguished from an independent contractor. The test is the existence of a right of *control* over the agent in respect of the *manner* in which his work is to be done. A servant is an agent who works under the supervision and direction of his employer; he is employed to obey his employer's orders from time to time. An independent contractor is one who is his own master; he is engaged to do certain work, but he exercises his own discretion as to the mode and time of doing it. A hospital board will accordingly be responsible for the negligent acts or omissions of a servant in the course of his employment. The servant must be in the employ of the board at the time the acts complained of are done.

Who of those persons appointed by hospitals are servants of the hospital? This question must be answered in respect of every individual or class of officers. The persons engaged in a hospital may for convenience be classified as follows: (1) Physician and surgeons (including house officers, anæsthetists, and specialists); (2) nursing staff; and (3) lay or non-professional staff.

With regard to the first named class it has been expressly decided (Hillyer v. Governors of St. Bartholomew's Hospital) that the relationship of master and servant does not exist between the governors of a hospital and the physicians and surgeons who give their services to the hospital. It was held that they are professional men, employed by a hospital to exercise their profession to the best of their abilities according to their own discretion: but in exercising it they are in no way under the orders nor bound to obey the directions of the hospital authorities. It is true that a hospital has power to dismiss these officers, but it has this power, not because they are servants, but because of its control over the hospital where their services are rendered. A staff surgeon or physician then is not an employee of the hospital but holds an independent professional relation; he, not the hospital, is liable for his acts, and by reverse reasoning the hospital would not be liable for injuries which he might suffer in the course of his work in the hospital. A medical superintendent is, however, more directly associated with the board. He is, in general, appointed by the board at a fixed salary under a special contract with the board, and usually has control over all departments of the hospital, and the treatment of the patients therein. It may be contended, however, that as far as the treatment of patients is concerned, he is not a servant of the board because he is not subject to the control of the board as to the mode of treatment he adopts. The degree of control which a board may exercise over a medical superintendent undoubtedly varies in different cases, but it is most unlikely that in every case a board would have the power of dictating in what way he should conduct operations or treat patients. This is entirely a matter for the superintendent in the exercise of his professional skill and knowledge. House officers are employees of the hospital when acting under the direction of the hospital authority, but they also hold a quasi-professional relationship, and in addition they have a special relation to the physician or surgeon whom they may be asissting. In Cooper v. Mirron and Another, a house officer was held liable for so extracting a tooth that a part broke off and passed down the windpipe. The accident was not reported to his senior; pneumonia set in, and the patient died.

With regard to the second class, the position of the nursing staff of a hospital is, however, not so clearly defined. They are engaged by the board at fixed salaries, their hours of attendance in the wards and general duties are prescribed by the board by whom they are paid and by whom they may be dismissed. These features point to the fact that they are servants of the board: for all general purposes this is undoubtedly the correct view, but they are not so for the purposes of operations and examinations by medical officers. Nurses (and indeed other officials) assisting at operations cease for the time being to be servants of the hospital inasmuch as they take their orders from the operating surgeons alone and not from the hospital authorities. Can they be deemed the servants of the board when attending patients in the wards and acting in their professional capacity? All nurses require a special training to fit them for their occupation, and it may be argued that they are not subject to the control of the board in the manner in which they do their work. In their treatment of, and attendance on, patients, they act either under the direction of physicians or in accordance with their professional skill and knowledge. The board is not, it is contended, in a position to dictate in what way the work is to be done. Although it fixes the hours, supplies necessary board and lodging, pays and dismisses nurses, it cannot control them in the exercise of their profession as nurses. From this point of view they are not the servants of the board in the course of any of their professional duties. The dicta of Kennedy L.J., in Hillyer v. St. Bartholomew's Hospital support this view. He classes nurses as experts along with physicians and surgeons, and states that, provided the board has been reasonably satisfied as to their competency, it will not be liable for their negligence. This of course refers only to the conduct of the staff in matters of *professional skill*, in which the board *neither do nor could not properly interfere* either by rule or supervision. The board would, it is contended, be legally responsible to the patients for the due performance of their servants within the hospital of their purely *ministerial or administrative duties*, such as for example, attendances of nurses in the wards, the summoning of medical aid in cases of emergency, the supply and service of food, and the like. The board ought to make, and invariably does make, its own regulations in respect of such matters of routine, and it is obviously legally responsible for their sufficiency, their propriety, and observance of them by their servants. The scope of these ministerial duties or matters of routine is difficult to define. It will generally be found that most of the duties of the nurse are professional, and required special skill or knowledge. In matters, however, which do not require special skill nor knowledge, nurses must be regarded as the servants of the board, and in such matters the board may properly interfere. These matters will be few in number, and a nurse will, therefore, in general not be the servant of the board.

All other officials and employees about the hospital are with certain exceptions, servants of the board. Exceptions occur when they are working under the exclusive control of physicians and surgeons and other medical and nursing experts.

The Duty and Obligations of the Board.

Although the board is not responsible for the negligence of its professional staff in the exercise of their profession, it is under the duty to see that the professional staff employed by it are competent. It undertakes that the patients in and attending the hospital will have competent advice and assistance. (Evans v. Liverpool Corporation). The governors of a hospital, by their admission of the patient to enjoy in the hospital the gratuitous benefit of its care, tacitly undertake that the patient whilst there shall be treated by experts, whether surgeons, physicians, or nurses, of whose professional competence the governors have taken reasonable care to assure themselves; and further, that these experts shall have at their disposal for the care and treatment of the patient fit, adequate, and proper apparatus and appliances. There is no right legal inference from the circumstances of the relation of hospital and patient that the hospital authority makes itself liable in damages if members of its professional staff, of whose competence there is no question, act negligently towards the patient in some matter of professional care or skill, or neglect to use intelligently in their treatment the apparatus or appliances which are at their disposal. If, then, a hospital board exercise reasonable care in the selection of its professional staff by requiring satisfactory evidence of their competency, it will not be liable subsequently for the negligence of its staff. If, of course, for any reasons it has good ground to doubt the competency of any member of its staff under circumstances which would justify it in dismissing such member, it should do so.

Paying Patients.

In Foote v. Shaw Stewart, an attempt was made to distinguish the circumstances from the St. Bartholomew's case, in respect that the Greenock Hospital authorities, by receiving a fee of £2 2s. from the patient, undertook that the treatment which she should *receive* from the doctors would be reasonably skilful and careful. Otherwise stated, this argument implied that *though* to the ordinary charity or non-paying patient the duty of the hospital was simply to provide the services of a competent staff of medical men, yet to a paying patient they were bound to ensure a special degree of medical care and attention, or a guarantee of skill on the part of the surgeon. The court held that, in the absence of a contract much more specific and *definite* than could be implied from the plaintiff's arguments, they could make no distinction between the two cases.

A MEDICAL JOURNAL FOR CUBA.

THE *Anales de la Facultad de Medicin y Farmacia*, of which the first two numbers have reached us, is described as a quarterly publication, started to record the work of the Medical Faculty of the University of Havana at a moment when it seems to be undergoing some reorganisation and reconstruction. Among the contributions there is none of outstanding importance, but several of considerable interest. Prof. P. Escudero, of Buenos Aires, states his views on "latent diabetes," which he differentiates from "diabetes occulta" by the fact that there is no hyperglycæmia; which, however, can be produced by a method of dieting which he has devised and terms blocking of the pancreas. The cases are characterised clinically by various chronic disorders, and can be cured by large doses of insulin, of which they are very tolerant. There are also in the first number papers on a case of benign giant-celled tumour of the metacarpals, endothelioma of the skin, prostatotomy in retention due to acute gonorrhœal infection, and the surgery of the thyroid. In the second number there is an article on a case of multiple myelomata in an infant beginning before 17 months of age and ending with albumosuria. Prof. Pardo Costello deals with the relation between herpes and varicella and concludes that it is accidental. Dr. Ostiz Machado describes some experiments on the production of nephritis in rabbits by administering sodium chloride with a vegetarian and milk diet respectively, and also by giving white lead. A paper in the first number on the selection of medical students is interesting as revealing the fact that the teaching schools of both North and South America are seriously hampered by the great and persistent increase in the number of students seeking to enter the medical profession, an increase out of proportion to the needs of the population, and in the Latin republics, at all events, partly due to social ambition.

THE POTENTIAL ENERGY OF THE FŒTUS.

A SOMEWHAT new conception of obstetrical mechanics is contained in a lecture delivered last year before the Obstetrical Society of Vienna by Dr. J. F. Beruti, of Buenos Aires, which has been published in the *Semana Médica* (April, 1928, p. 937). Starting from the work of Sellheim, of Leipzig, the author claims that he does not go far enough in his conception of the fœtus as an active agent in parturition. With the aid of ingenious models made to represent the mechanism of labour he believes he can show that there are two kinds of active fœtal reaction, which originate from the double resistance of the maternal canal and the fœtus itself. The first is the potential energy or elasticity of the fœtus and the second is muscular contraction. The second factor is said to be the cause of the change of position of the head sometimes observed during labour in the pauses between uterine contractions. Little other clinical evidence is adduced in favour of Dr. Beruti's view.

APPARATUS FOR INDUCING ARTIFICIAL PNEUMOTHORAX.

Dr. F. de V. Kováts[1] describes and illustrates a new instrument which appears to be a definite advance on those now employed for the induction of artificial pneumothorax. It consists of two cannulæ, one of which, having a blunt end and a lateral aperture, fits closely into the other, which has a sharp point and a terminal opening. The other ends of the cannulæ are so arranged that by turning a flange the inner cannula takes up one of three positions. In the first position the blunt end of the inner cannula lies wholly within the outer; in the second the blunt end of the inner cannula is made to project beyond the sharp end of the outer, but the lateral aperture is not exposed; in the third position, by a further turn of the flange, this aperture becomes exposed.

The technique for the induction of pneumothorax is as follows. The instrument is attached to the pneumothorax apparatus, and with the cannulæ in the first position the needle is pushed through the skin almost down to the parietal pleura. A turn of the flange allows the blunt end of the inner cannula to be pushed beyond the sharp point of the outer, and the pleura is then punctured with the blunt end, after which the flange is again turned to expose the lateral aperture of the inner cannula to the pleural cavity. The manometer at once registers the intrapleural pressure and the air can then be injected.

The advantages of the apparatus appear to be: (1) the oscillations of the manometer indicate that the pleural space has been reached as soon as the parietal pleura is pierced; (2) the danger of puncture of the lung is lessened by the fact that the inner cannula has a blunt end; (3) the lateral aperture cannot be blocked by pieces of skin or other tissue; (4) no manipulation of the needle is necessary after the pleural space has been reached; (5) the possibility of air embolism is almost negligible; and (6) the same apparatus may be used for both the induction and the refills of the pneumothorax cavity.

WOMEN'S HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—The result of our yearly appeal in the press has been of such value in the past that we trust you will once more allow us space in which to plead the cause of this Fund. Just now many fortunate people are engaged in the all-important task of making plans for their summer holiday—a delightful and necessary change of scene. We would ask them not to forget the many hundreds of women in London who have little chance of getting away from the monotony of their daily life, who in many cases have never tasted the joy of a seaside or country holiday, and whose health is suffering in consequence. This Fund, which was founded in 1895, organises every summer a fortnight's holiday at the seaside for many of these tired women who contribute what they can towards the full cost (£3 for a fortnight including railway fare). Last year 864 women were sent away and 500 of these took their babies. Will all holiday-makers help us to increase the number this year by sending some contribution, however small, to the Secretary, Women's Holiday Fund, Denison House, Vauxhall Bridge-road, S.W. 1.

We are, Sir, yours faithfully,
A. F. LONDON.
MANUEL L. BIDWELL,
J. SCOTT LIDGETT,
HELEN A. POWNALL
(Chairman of Executive Committee)

76, Denison House, 296, Vauxhall Bridge-road, S.W.,
July 10th, 1928.

AN INTERESTING DINNER.

A DINNER was given by the proprietors of Eno's Fruit Salt on Friday, July 6th, at the Savoy Hotel, Colonel Alhusen, the chairman of the Company, presiding over a large gathering. The occasion was made interesting by the opening which it gave for admirable speeches from Sir Robert Horne, late Chancellor of the Exchequer, and Mr. Amery, the Colonial Minister, who approached the subject of honest trading from completely different angles, but pointed out alike that in its success resided the finest promise for the conduct of imperial affairs. Sir Robert Horne, from vast personal experience, spoke of the value to the British trader of maintaining and extending relations with the Dominions, and probably surprised his audience by stating the ratios of trade between the mother country and the continent on the one hand, and the mother country and our dependencies on the other. The conclusion that it is to the interest of all to promote the colonial markets was inevitable on his showing. To the guests at the dinner there was presented a charming brochure written by a well-known group of journalists and experts and illustrated, among others, by Mr. Arthur Rackham, Mr. E. J. Sullivan, Mr. Lewis Baumer, and Mr. Bernard Partridge. Save Mr. Partridge's introductory cartoon both articles and pictures were deliberately humorous, but at the same time a clear picture of a leading figure in the early Victorian era of commerce emerged in a contemporary environment.

Messrs. H. K. Lewis, of 136, Gower-street, London, W.C., have published a pamphlet setting out the services which they render to the medical profession, and describing the progress of their business since its foundation in 1844. Besides their bookselling department, which executes orders by post, they maintain a large circulating library intended to meet the needs of those who wish to keep in touch with the latest opinions and discoveries. A monthly list of new books and new editions added to the library is sent regularly post free, and a reading and writing room for subscribers is provided. The library contains some 30,000 volumes, and the complete catalogue, revised to December of last year, with upwards of 18,000 titles, will be published shortly. Surplus copies of books withdrawn from circulation are sold at reduced prices in the second-hand department, 140, Gower-street, where a large stock of books is always kept. Scarce books or those out of print are advertised for without charge and reported when found.

The Radiotherapy of Cancer.—The personnel of the subcommittee of experts charged by the Cancer Commission of the League of Nations with the study of radiotherapy of cancer was given in THE LANCET last week. The description of Mr. Comyns Berkeley should have run: Director of the Gynæcological Service, Middlesex Hospital Cancer Charity.

"Swimeezi" Bathing Costume.—We are informed that the address of the Institute of Patentees referred to in our notice of the above invention is now at 39, Victoria-street, Westminster, S.W. 1.

Dedication Address

ON

MEDICAL AND NURSING SERVICE.

Delivered on June 26th at the Inauguration of the Hospital and Nursing Centre established by the Frontier-Nursing Service of Kentucky

BY SIR LESLIE MACKENZIE, M.A., M.D., LL.D.,
FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, EDINBURGH; FELLOW OF THE ROYAL SOCIETY OF EDINBURGH; EX-MEMBER OF THE SCOTTISH BOARD OF HEALTH; CROWN NOMINEE FOR SCOTLAND ON THE GENERAL MEDICAL COUNCIL OF GREAT BRITAIN.

THE Frontier Nursing Service already know the work of the pioneers in preparing the way for this assembly of inauguration and dedication. It is a story full of adventure, sacrifice, passionate enthusiasm and splendid initiative. When, some years ago, Mrs. Mary Breckinridge came to us in Scotland to see how we had faced a similar problem in medical service and nursing, we were filled with a new sense of the significance of the work we had tried to do in the thinly peopled and difficult areas of Scotland. When, therefore, I was invited by the Frontier Nursing Service of Kentucky to give verbal form to the dedication of the hospital and nursing system now established in these mountains, I felt, indeed, a glow of supreme satisfaction that our work in Scotland had found an echo in the great spaces and mountains of an American Commonwealth. The invitation was a call of the Highlands to the Highlands. It is a symbol of kinship in feeling and outlook. It is the lightning spark that reveals the essential unity of our culture. An invitation coming with this warmth and delicacy of imagination, I could not refuse and, in the name of the Scottish Highlands, I accepted it with my whole heart. When my wife and I, more than 35 years ago, dedicated our lives to the service of Scotland, we could not foresee that now, when our work is nearing its end, we should be gladdened and newly inspired by this fine compliment to our Northern Kingdom. But the privilege and honour you have conferred upon us will make it easier for us to pass into the twilight of our lives, remembering the lights and sounds and silences of these historic creeks and mountain passes and pathways.

Perhaps, however, my presence here is due to a deeper cause. I was born in Easter Ross, within sound of the North Sea and within sight of the mountains of Ross and Inverness. From my earliest memories, I have known something of the difficulties of Highland life, and when I passed into the National Service I came to the health problems of the Highlands and Islands with some understanding of the inner minds and aspirations of the people, of the difficulties due to a long and losing struggle with poverty and of the problems created by centuries of European invasion, whose story is lost in legend and mystery. The more one studies things as they are to-day, the more one is impressed with the infinite complexities of the growth of peoples. At this hour, the ten million acres of the Highlands and Islands of Scotland have scattered over them a population less than the city of Edinburgh. In our Highland area, as defined by statute in the Highlands and Islands Medical Service Act, the peoples number approximately 320,000 only. But these are scattered in islands as far north as the Shetland group, about 120 miles from the mainland of Scotland; *the Orkney* group, mostly visible from the mainland; the Fair Isle, a solitary island of some 200 people lying between the two groups; the remote island rock of Foula with perhaps another 200; the Out Skerries with 30 or 40 families, and then the Outer Hebrides, from Lewis to Barra, with a total population of 44,000, or the remote Atlantic rock of St. Kilda, where the population within my official life-time of 27 years has fallen from 76 to 45. No doubt, it is these varieties of difficult administration that have fascinated Mrs. Breckinridge in looking for a parallel with the difficulties of the Kentucky mountains, and there are many parallel conditions in the two countries. But most striking, perhaps, is the parallel in character and outlook, the disposition due to the necessity of facing the forces of nature alone, the relative sterility of the hills and glens, as well as the ferocities of the wind and the sea.

AN ADMINISTRATIVE DIFFICULTY.

From the map it is easy to see why the Highlands and Islands are an administrative difficulty. When a population approximately equal to the city population of Edinburgh is scattered over three-fourths of Scotland and parcelled out among the hills, the valleys and islands, the mere geographical dispersal gives rise to innumerable and persistent local problems of feeding, housing, and transport. This would be true even if the dispersed people all belonged to a single variety of civilisation. But in the Highlands and Islands are to be found strata of many civilisations. There are differences in belief, in custom, in variety of segregation, in economic sufficiency, in race, in political affinity. In every Government department—poor law, lunacy, public health, agriculture, fisheries, prisons—all these factors have to be reckoned with, and unending records show how difficult the individual problems are. Among the western islands—the Hebrides—there is scarcely one that has not its little internal war between the local middle-man and the island producer, or between the crofter and the big estate, or again, between the land interest and the industrialised fishing islands or towns, or between sections of the same island, where, perhaps, racial traditions block the way to complete assimilation, or again, between different religious groups, each claiming divine rightness for its own doctrines. Such mental segregations and specialisations often block the way to successful administration. These, and such as these, are the motive forces that have generated the complex machinery of our existing administration. The variations in the machine are reflected in the long series of commissions and committees that have had to investigate every phase of social life in the Highlands and Islands. The reports are only a record of efforts to compose the struggles of these variously civilised groups to maintain themselves, first against nature and next against their domestic enemies. Only a generation or two ago, it was " war to the knife " in the literal sense. To-day the struggles are as keen, but the methods of fighting are more subtle. But the kind of fact we constantly run up against is this: that conscription made almost no difference to the island of Lewis, with its 28,000 inhabitants, because nearly all the men of fighting age had already joined some fighting unit of land or sea; or, again, that one of the island groups most affected with tuberculosis sent relatively high proportions of men to the Navy; or that, in one parish of some seven thousand people, there are said to be 22 " places of worship," representing at least four, if not five or six, Protestant denominations; or, once more, that the Highlands and Islands send to the Universities of Scotland from 10 to 12 times as many persons in proportion to population as the rest of Scotland. The last fact I learned many years ago from my last schoolmaster, Dr. Dey, late Rector of the Grammar School of Old Aberdeen, who had the arranging of secondary departments for the Highlands Committee. A tutor of Oriel College, Oxford, once told me that the best philosophical student he had had in 30 years came from Stornoway. Recently, a book on the nature of " community " came on the philosophical world from "a young Canadian professor," who went to Canada, via Oxford, from Lewis, and is now a professor in Columbia University. How easy it would be to load pages with such facts, or with flashes of beauty from the lochs or voes, or romantic tales of old adventure, or

A MEDICAL JOURNAL FOR CUBA.

THE *Anales de la Facultad de Medicin y Farmacia*, of which the first two numbers have reached us, is described as a quarterly publication, started to record the work of the Medical Faculty of the University of Havana at a moment when it seems to be undergoing some reorganisation and reconstruction. Among the contributions there is none of outstanding importance, but several of considerable interest. Prof. P. Escudero, of Buenos Aires, states his views on "latent diabetes," which he differentiates from "diabetes occulta" by the fact that there is no hyperglycæmia; which, however, can be produced by a method of dieting which he has devised and terms blocking of the pancreas. The cases are characterised clinically by various chronic disorders, and can be cured by large doses of insulin, of which they are very tolerant. There are also in the first number papers on a case of benign giant-celled tumour of the metacarpals, endothelioma of the skin, prostatotomy in retention due to acute gonorrhœal infection, and the surgery of the thyroid. In the second number there is an article on a case of multiple myelomata in an infant beginning before 17 months of age and ending with albumosuria. Prof. Pardo Costello deals with the relation between herpes and varicella and concludes that it is accidental. Dr. Ostiz Machado describes some experiments on the production of nephritis in rabbits by administering sodium chloride with a vegetarian and milk diet respectively, and also by giving white lead. A paper in the first number on the selection of medical students is interesting as revealing the fact that the teaching schools of both North and South America are seriously hampered by the great and persistent increase in the number of students seeking to enter the medical profession, an increase out of proportion to the needs of the population, and in the Latin republics, at all events, partly due to social ambition.

THE POTENTIAL ENERGY OF THE FŒTUS.

A SOMEWHAT new conception of obstetrical mechanics is contained in a lecture delivered last year before the Obstetrical Society of Vienna by Dr. J. F. Beruti, of Buenos Aires, which has been published in the *Semana Médica* (April, 1928, p. 937). Starting from the work of Sellheim, of Leipzig, the author claims that he does not go far enough in his conception of the fœtus as an active agent in parturition. With the aid of ingenious models made to represent the mechanism of labour he believes he can show that there are two kinds of active fœtal reaction, which originate from the double resistance of the maternal canal and the fœtus itself. The first is the potential energy or elasticity of the fœtus and the second is muscular contraction. The second factor is said to be the cause of the change of position of the head sometimes observed during labour in the pauses between uterine contractions. Little other clinical evidence is adduced in favour of Dr. Beruti's view.

APPARATUS FOR INDUCING ARTIFICIAL PNEUMOTHORAX.

Dr. F. de V. Kováts[1] describes and illustrates a new instrument which appears to be a definite advance on those now employed for the induction of artificial pneumothorax. It consists of two cannulæ, one of which, having a blunt end and a lateral aperture, fits closely into the other, which has a sharp point and a terminal opening. The other ends of the cannulæ are so arranged that by turning a flange the inner cannula takes up one of three positions. In the first position the blunt end of the inner cannula lies wholly within the outer; in the second the blunt end of the inner cannula is made to project beyond the sharp end of the outer, but the lateral aperture is not exposed; in the third position, by a further turn of the flange, this aperture becomes exposed.

The technique for the induction of pneumothorax is as follows. The instrument is attached to the pneumothorax apparatus, and with the cannulæ in the first position the needle is pushed through the skin almost down to the parietal pleura. A turn of the flange allows the blunt end of the inner cannula to be pushed beyond the sharp point of the outer, and the pleura is then punctured with the blunt end, after which the flange is again turned to expose the lateral aperture of the inner cannula to the pleural cavity. The manometer at once registers the intrapleural pressure and the air can then be injected.

The advantages of the apparatus appear to be: (1) the oscillations of the manometer indicate that the pleural space has been reached as soon as the parietal pleura is pierced; (2) the danger of puncture of the lung is lessened by the fact that the inner cannula has a blunt end; (3) the lateral aperture cannot be blocked by pieces of skin or other tissue; (4) no manipulation of the needle is necessary after the pleural space has been reached; (5) the possibility of air embolism is almost negligible; and (6) the same apparatus may be used for both the induction and the refills of the pneumothorax cavity.

WOMEN'S HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—The result of our yearly appeal in the press has been of such value in the past that we trust you will once more allow us space in which to plead the cause of this Fund. Just now many fortunate people are engaged in the all-important task of making plans for their summer holiday—a delightful and necessary change of scene. We would ask them not to forget the many hundreds of women in London who have little chance of getting away from the monotony of their daily life, who in many cases have never tasted the joy of a seaside or country holiday, and whose health is suffering in consequence. This Fund, which was founded in 1895, organises every summer a fortnight's holiday at the seaside for many of these tired women who contribute what they can towards the full cost (£3 for a fortnight including railway fare). Last year 864 women were sent away and 500 of these took their babies. Will all holiday-makers help us to increase the number this year by sending some contribution, however small, to the Secretary, Women's Holiday Fund, Denison House, Vauxhall Bridge-road, S.W. 1.

We are, Sir, yours faithfully,

A. F. LONDON.
MANUEL L. BIDWELL,
J. SCOTT LIDGETT,
HELEN A. POWNALL
(Chairman of Executive Committee)

76, Denison House, 296, Vauxhall Bridge-road, S.W.,
July 10th, 1928.

AN INTERESTING DINNER.

A DINNER was given by the proprietors of Eno's Fruit Salt on Friday, July 6th, at the Savoy Hotel, Colonel Alhusen, the chairman of the Company, presiding over a large gathering. The occasion was made interesting by the opening which it gave for admirable speeches from Sir Robert Horne, late Chancellor of the Exchequer, and Mr. Amery, the Colonial Minister, who approached the subject of honest trading from completely different angles, but pointed out alike that in its success resided the finest promise for the conduct of imperial affairs. Sir Robert Horne, from vast personal experience, spoke of the value to the British trader of maintaining and extending relations with the Dominions, and probably surprised his audience by stating the ratios of trade between the mother country and the continent on the one hand, and the mother country and our dependencies on the other. The conclusion that it is to the interest of all to promote the colonial markets was inevitable on his showing. To the guests at the dinner there was presented a charming brochure written by a well-known group of journalists and experts and illustrated, among others, by Mr. Arthur Rackham, Mr. E. J. Sullivan, Mr. Lewis Baumer, and Mr. Bernard Partridge. Save Mr. Partridge's introductory cartoon both articles and pictures were deliberately humorous, but at the same time a clear picture of a leading figure in the early Victorian era of commerce emerged in a contemporary environment.

Messrs. H. K. Lewis, of 136, Gower-street, London, W.C., have published a pamphlet setting out the services which they render to the medical profession, and describing the progress of their business since its foundation in 1844. Besides their bookselling department, which executes orders by post, they maintain a large circulating library intended to meet the needs of those who wish to keep in touch with the latest opinions and discoveries. A monthly list of new books and new editions added to the library is sent regularly post free, and a reading and writing room for subscribers is provided. The library contains some 30,000 volumes, and the complete catalogue, revised to December of last year, with upwards of 18,000 titles, will be published shortly. Surplus copies of books withdrawn from circulation are sold at reduced prices in the second-hand department, 140, Gower-street, where a large stock of books is always kept. Scarce books or those out of print are advertised for without charge and reported when found.

The Radiotherapy of Cancer.—The personnel of the sub-committee of experts charged by the Cancer Commission of the League of Nations with the study of radiotherapy of cancer was given in THE LANCET last week. The description of Mr. Comyns Berkeley should have run: Director of the Gynæcological Service, Middlesex Hospital Cancer Charity.

"Swimeezi" Bathing Costume.—We are informed that the address of the Institute of Patentees referred to in our notice of the above invention is now at 39, Victoria-street, Westminster, S.W. 1.

Dedication Address

ON

MEDICAL AND NURSING SERVICE.

Delivered on June 26th at the Inauguration of the Hospital and Nursing Centre established by the Frontier-Nursing Service of Kentucky

BY SIR LESLIE MACKENZIE, M.A., M.D., LL.D.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS, EDINBURGH; FELLOW OF THE ROYAL SOCIETY OF EDINBURGH; EX-MEMBER OF THE SCOTTISH BOARD OF HEALTH; CROWN NOMINEE FOR SCOTLAND ON THE GENERAL MEDICAL COUNCIL OF GREAT BRITAIN.

THE Frontier Nursing Service already know the work of the pioneers in preparing the way for this assembly of inauguration and dedication. It is a story full of adventure, sacrifice, passionate enthusiasm and splendid initiative. When, some years ago, Mrs. Mary Breckinridge came to us in Scotland to see how we had faced a similar problem in medical service and nursing, we were filled with a new sense of the significance of the work we had tried to do in the thinly peopled and difficult areas of Scotland. When, therefore, I was invited by the Frontier Nursing Service of Kentucky to give verbal form to the dedication of the hospital and nursing system now established in these mountains, I felt, indeed, a glow of supreme satisfaction that our work in Scotland had found an echo in the great spaces and mountains of an American Commonwealth. The invitation was a call of the Highlands to the Highlands. It is a symbol of kinship in feeling and outlook. It is the lightning spark that reveals the essential unity of our culture. An invitation coming with this warmth and delicacy of imagination, I could not refuse and, in the name of the Scottish Highlands, I accepted it with my whole heart. When my wife and I, more than 35 years ago, dedicated our lives to the service of Scotland, we could not foresee that now, when our work is nearing its end, we should be gladdened and newly inspired by this fine compliment to our Northern Kingdom. But the privilege and honour you have conferred upon us will make it easier for us to pass into the twilight of our lives, remembering the lights and sounds and silences of these historic creeks and mountain passes and pathways.

Perhaps, however, my presence here is due to a deeper cause. I was born in Easter Ross, within sound of the North Sea and within sight of the mountains of Ross and Inverness. From my earliest memories, I have known something of the difficulties of Highland life, and when I passed into the National Service I came to the health problems of the Highlands and Islands with some understanding of the inner minds and aspirations of the people, of the difficulties due to a long and losing struggle with poverty and of the problems created by centuries of European invasion, whose story is lost in legend and mystery. The more one studies things as they are to-day, the more one is impressed with the infinite complexities of the growth of peoples. At this hour, the ten million acres of the Highlands and Islands of Scotland have scattered over them a population less than the city of Edinburgh. In our Highland area, as defined by statute in the Highlands and Islands Medical Service Act, the peoples number approximately 320.000 only. But these are scattered in islands as far north as the Shetland group, about 120 miles from the mainland of Scotland; the Orkney group, mostly visible from the mainland: the Fair Isle, a solitary island of some 200 people lying between the two groups; the remote island rock of Foula with perhaps another 200; the Out Skerries with 30 or 40 families, and then the Outer Hebrides, from Lewis to Barra, with a total population of 44,000, or the remote Atlantic rock of St. Kilda, where the population within my official life-time of 27 years has fallen from 76 to 45. No doubt, it is these varieties of difficult administration that have fascinated Mrs. Breckinridge in looking for a parallel with the difficulties of the Kentucky mountains, and there are many parallel conditions in the two countries. But most striking, perhaps, is the parallel in character and outlook, the disposition due to the necessity of facing the forces of nature alone, the relative sterility of the hills and glens, as well as the ferocities of the wind and the sea.

AN ADMINISTRATIVE DIFFICULTY.

From the map it is easy to see why the Highlands and Islands are an administrative difficulty. When a population approximately equal to the city population of Edinburgh is scattered over three-fourths of Scotland and parcelled out among the hills, the valleys and islands, the mere geographical dispersal gives rise to innumerable and persistent local problems of feeding, housing, and transport. This would be true even if the dispersed people all belonged to a single variety of civilisation. But in the Highlands and Islands are to be found strata of many civilisations. There are differences in belief, in custom, in variety of segregation, in economic sufficiency, in race, in political affinity. In every Government department—poor law, lunacy, public health, agriculture, fisheries, prisons—all these factors have to be reckoned with, and unending records show how difficult the individual problems are. Among the western islands—the Hebrides—there is scarcely one that has not its little internal war between the local middle-man and the island producer, or between the crofter and the big estate, or again, between the land interest and the industrialised fishing islands or towns, or between sections of the same island, where, perhaps, racial traditions block the way to complete assimilation, or again, between different religious groups, each claiming divine rightness for its own doctrines. Such mental segregations and specialisations often block the way to successful administration. These, and such as these, are the motive forces that have generated the complex machinery of our existing administration. The variations in the machine are reflected in the long series of commissions and committees that have had to investigate every phase of social life in the Highlands and Islands. The reports are only a record of efforts to compose the struggles of these variously civilised groups to maintain themselves, first against nature and next against their domestic enemies. Only a generation or two ago, it was " war to the knife " in the literal sense. To-day the struggles are as keen, but the methods of fighting are more subtle. But the kind of fact we constantly run up against is this: that conscription made almost no difference to the island of Lewis, with its 28,000 inhabitants, because nearly all the men of fighting age had already joined some fighting unit of land or sea; or, again, that one of the island groups most affected with tuberculosis sent relatively high proportions of men to the Navy; or that, in one parish of some seven thousand people, there are said to be 22 " places of worship," representing at least four, if not five or six, Protestant denominations; or, once more, that the Highlands and Islands send to the Universities of Scotland from 10 to 12 times as many persons in proportion to population as the rest of Scotland. The last fact I learned many years ago from my last schoolmaster, Dr. Dey, late Rector of the Grammar School of Old Aberdeen, who had the arranging of secondary departments for the Highlands Committee. A tutor of Oriel College, Oxford, once told me that the best philosophical student he had had in 30 years came from Stornoway. Recently, a book on the nature of " community " came on the philosophical world from "a young Canadian professor," who went to Canada, via Oxford, from Lewis, and is now a professor in Columbia University. How easy it would be to load pages with such facts, or with flashes of beauty from the lochs or voes, or romantic tales of old adventure, or romantic songs from the living old world of music revealed to us by Mrs. Kennedy Fraser in her "Songs of the Hebrides"!

These things I name merely because they must be thought of as signs of the informing spirit whose organised embodiment for the purposes of our rough administrations we must state in crudely practical terms. Machines do not move of themselves, even Government machines. But the efforts of generation after generation to bring the Highlands and Islands within the working polity of modern Scotland make a pathetic record, whether we think of the suppressed clan system with its tribal wars, or the Scots Poor Law, beginning in 1424, and failing, by branding on the cheek, as it fails to-day by the poorhouse "test," to master or provide for the marginal citizen, or again, "the various crofter clearances," whose memory, in some glens and straths, is as bitter to-day as on the day they happened, or the abortive efforts to clean the islands of their people by emigration, or the failure of the potato crop, or the crofter's commissions, fisheries committees, medical committees, medical reports, attempted colonisations, medical service, and a dozen other things. These islands and glens have sent hundreds upon hundreds to the Western Continent, and to-day, among these mountains, we are in the neighbourhood of their descendants and we feel the atmosphere of the Scottish home. I have read something of the story of Daniel Boone (a man of Cornish stock) and the other pioneers, who fought their way from Pennsylvania down the valleys to the Yadkin and over these mountains into the heart of Kentucky, to help in forming the Commonwealth you now enjoy. I should like also to believe that, in these southern lands as well as in the harder north, the races and traditions of the Scottish Highlanders and Islanders have done something to help in the civilisations of the west.

FUNDAMENTAL UNITY OF THE SCOTTISH AND KENTUCKY PROBLEMS.

In one respect, the problem of the Kentucky mountains is essentially the same as the problem of the Scottish Highlands and Islands—namely, that the financial resources of the thinly peopled areas are rarely, if ever, sufficient to provide the same adequate services that the larger groups of population enjoy. That was the root of our problem in Scotland. It is the root of the problem in the Commonwealth of Kentucky. With us, it is largely a difficulty of the sea and its dangerous sounds, some of them impassable for weeks at a time. With you, it is largely a matter of land and river transport, where, however, the isolation may be just as great. Wherever we find the thinly populated islands or mountains, there we find difficulty in providing sufficient service. When we went the rounds of the Orkney and Shetland Islands, and the Hebrides, and many mountainous areas on the mainland, we had it said to us by many that the Highlanders were fatalists; that, in the last stages of life, they lost hope and were content to die, and that, therefore, medical or nursing service would be of little use. To a Highlander born in the Highlands this diagnosis of the social condition was only a proof of the Lowland failure to understand. How many a case I have heard of where the term "fatalism" was only a name for the proud personal independence that preferred death to the asking of favours! When, in the end, medical and nursing service has been provided, and the people feel that it is their own, they come forward in greater and greater numbers to utilise and enjoy the services provided through the State for themselves and their children. When the new movement began, even the doctors that went to the remote places were often deficient in training, or they were the men that had failed elsewhere. To-day, whenever a medical practice falls vacant anywhere, tens and twenties, and thirties and forties of medical men come forward, and the localities can choose from a highly trained body of medical practitioners. That is our answer to all that was said to us by the people that did not understand. You are having the same success as we had, and for the same reasons.

BIOLOGICAL GROUNDWORK OF MEDICAL AND NURSING SERVICE: OUR FIRST TWO YEARS.

But let us look behind the administrative machine. Why is it necessary to take such immense trouble with the first stages of life? Why should the young infant require of us so much more active help and tender consideration than the child of later ages? To this question it is not easy in a few words to give an adequate answer. For here we are face to face with the fundamental problem of social life. The solution of it involves all that the world knows of biological theory. There must be centred in the new-born infant some fundamental fact that makes it, at that stage, different from every other human being. The great miracle of birth is protected by the most powerful of human motives—the love of the mother for her child. It is a motive stronger than the fear of death. In all ages of the world, the love of a mother for her child has commanded the worship of mankind. If you think for a moment, you will understand that nothing less can preserve the life of the helpless new-born child. All our institutions for the welfare of mothers and their children have their taproot in the one great fact that, when the child dies, the race dies, and when the race dies, the great fight between life and nature is over.

It is, therefore, our duty to do what we can to guide the mother and child safely through the many dangers that threaten them in the months of expectancy and in the few critical days or hours of the confinement. If I chose, I could take from the records of the maternity hospitals long tales of damaged mothers, whose lives have been made miserable for ever by inadequate attention, or by unskilled handling, or by the necessity for the premature resumption of household duty, or by some other unfortunate combination of preventable causes. But we are not now thinking of the mothers affected with disease or deformity; we are thinking only of the normal expectant mother, who wishes to have no misgiving when the hour of her confinement comes, and who ought to have the organised care that is available to her only in the maternity home or at the hands of the scientifically trained doctor or nurse.

But there is a more fundamental reason for doing all we can to extend all the resources of the community to the care of the young human being. Consider what happens during the first year of a child's life. Its rate of growth is phenomenally rapid. For the first year, its rate of increase is 200 per cent. In its second year, the rate falls to 20 per cent. Until the age of 12, the percentage-rate of growth falls off, rising a little at 13, and then sinking until it comes almost to zero somewhere between 20 and 23. This is for boys. For girls the pace is not quite so rapid, but is practically the same. Recently, it has been held and, on the whole, demonstrated by biologists that senescence—that is, the process of growing old—varies in speed at different periods of life. Ordinarily, we are accustomed to think of senescence as applying only to men and women that have passed middle life. But it is now known that the process of senescence and rejuvenescence is a phenomenon applicable to all ages and to all growing organisms. Briefly, senescence is a process whereby the growing organism carries on with it certain products that ultimately clog the machinery and produce death. Through life, in various ways, there are periods of rejuvenescence, when those accumulated products may be thrown off and a person takes, as we say, a new lease of life. It is not possible here to discuss the theory fully; but the important point in it is that the process of senescence—that is, quite literally, the process of growing old and incapable of rejuvenescence—goes on most rapidly in the early years of life. As Mr. Charles Manning Child, of the University of Chicago, in his wonderful research on "Senescence and Rejuvenescence," puts it: "The rate of senescence is highest in youth and lowest in advanced life." The process of senescence is most rapid when the process of growth is most rapid. As, therefore, growth is most rapid in the earliest period of infancy, the child, during that period, may correctly be said to be racing at full speed into old age. Put otherwise, this means that in the period from conception to the end of the second year the child's organs and faculties become rapidly so fixed, that if his nurture through that period is not sound he will suffer disproportionately for all the rest of his days. Anyone that has watched the birth and nurture of young animals can tell you that if the infant animal does not get a good and correct start he never develops to the full stature or power of an adult. It is the same with human beings. Recently, too, the researches into diet have shown that the young and rapidly growing infant is peculiarly susceptible to the influence of extraordinarily minute quantities of particular food factors. The absence of an infinitesimal amount of a given substance will end in the production of rickets or scurvy. These well-known facts confirm the general conclusion of the biologists that the first months of life are of immense potency in determining the whole future course of individual development. Probably, if we could secure that our expectant mothers shall be properly fed and that they shall be fit to feed their new-born infants, we should not, later in life, have to spend fortunes in preserving our teeth or in procuring substitutes. That is only one very gross illustration of what I mean. But, broadly, the fact that the beginnings of all the child's organs are laid in the first few months after conception, and that the pace of his growth during the first year or two determines his healthiness or unhealthiness for the rest of his life, should alone be enough to justify us in focusing upon the early hours and weeks and months of infancy all the science and skill that we are able to command.

How Scotland has Faced the Problem of the Highlands and Islands.

It is not possible to give details of all our schemes. But the essence of the case is this: over 27 years ago we knew from experience that public health problems, like infectious disease, tuberculosis, typhoid fever, typhus fever, and the many others, could not be sufficiently provided for in the Highlands and Islands without national assistance. When the National Insurance Act of 1911 was passed, the Highlands and Islands, being largely a land of small holders, not of wage-earners, could not provide a sufficient population, even of insured wage-earners, to secure the benefits under the new Statute. It then became obvious to everybody in power, as it had been to the experts for years before, that, as in education so in health, the resources of the Highlands were inadequate for certain primary purposes. When, however, the first Insurance Act was passed, money was made available by Parliament and, on the basis of the Dewar Committee's Report, the Highlands and Islands Board was constituted. This Board was afterwards absorbed into the Scottish Board of Health. Parliament had voted a sum of £42,000 to accumulate year after year. This was before the war. Unfortunately, the difficulties of the war compelled us to stop the accumulation of capital and to expend it in such services as were possible in a time when every difficulty was at its greatest. Doctors by the score had to serve in the Army. We had to provide such substitutes as were available. But the large schemes we had prepared had to remain for a more favourable moment. Since the war, however, the projected developments are progressively appearing. In the year 1927, for example, we spent £70,000—that is, about 350,000 dollars—in the various medical services and nursing services. The primary objective of the whole system is so to adjust the service that the doctor shall be able to attend a patient 25, or 30, or 40 miles distant, or across a difficult sound or loch on the same terms as he would attend the people in his immediate neighbourhood. We aimed at eliminating from the charges the factor of distance. To do this we had to subsidise many doctors for their loss of fees. In other areas, single practice areas, we make up to the doctor a sufficient salary. In very poor areas we guarantee to the doctor a minimum salary that will attract good men and enable them to educate their families and to maintain their own professional education. In these types of service we spend £43,000 a year—that is, about 165,000 dollars. On nursing services we spend £13,300 a year, or over 66,000 dollars. We help with telegraphs and telephones. We subsidise the tuberculosis scheme. But perhaps the most important development of the whole system is the provision of operating surgeons for important localities. For instance, we provide a consultant operating surgeon for the Shetland group of islands, at a salary of about £900 a year, plus special earnings. In the Island of Lewis we similarly maintain an operating surgeon. In that island we have contributed £12,000 (60,000 dollars) to the extension of an admirable cottage hospital, which was opened a few weeks ago by the Under Secretary of State for Scotland. This serves a community of over 30,000 people. In both Lewis and Shetland these hospitals are maintained by voluntary subscriptions. A similar scheme is afoot for the Orkney group of islands. It is certain that in the next few years the scheme for providing operating surgeons will be extended. The young men appointed are carefully selected from the great medical schools. They must have a wide basis of surgical experience. It is gratifying to record that in the two instances up to date the people have come forward in a marvellous way. The operations performed run into hundreds. The medical men of the locality work cordially with the consultant surgeon. In all those island groups, also, there is a county medical officer of health, who sees to the medical examination and treatment of the school-children and the pre-school-children. The consultant surgeon thus becomes an integral part of the general medical and preventive service of the community. It is needless to say that all these medical services are supplemented by trained nurses. In fact, it is worth noting that in the Highlands and Islands Medical Service Act, under which Parliament voted the original grant, the term "medical service" specifically includes nursing service. So far as I know, this is the first time in a British Statute that nursing service has been included as a specific part of medical service. Doctors' houses and nurses' houses can be provided under the scheme and many such houses have been provided. Our aim is, where necessary, to provide at the nurses' house accommodation for one or more sick cases when the distance between her and her work is too great.

The Highlands and Islands medical service system began to operate effectively in 1914. Since that date to the end of 1927; we have spent nearly £660,000 (that is something over 3,000,000 dollars). Of this total, nearly £500,000 (say, 2,500,000 dollars) has been spent on medical service alone. Nursing associations have been subsidised to the extent of £95,000 (say, 475,000 dollars). The full details of all the scheme are in a form that can be easily studied by any person concerned with similar problems. This is what the small Northern Kingdom is doing for a handful of 320,000 people.

The Frontier Nursing Service.

I have been speaking of Scotland, but I have been thinking of Kentucky. With you, as with us, the mother and child demand intensive care. With you, as with us, there is the ever-recurring tragedy of hardship and death. Think what it means when a family loses the mother. The infant is robbed of its nurse; the other children are robbed of their first friend and teacher; the husband is robbed of his companion and confidant. The death of the mother means the maximum of unhappiness to the family she leaves. It is in this light that we must study the facts and in this light the facts are like no others. To preserve the life of mother and child is the problem before the Frontier Nursing Service. It needs only to be put into words to command the interest and sympathy of every humanist.

This hospital is the radiating centre of the nursing service in these mountains. The maxim of the trained nurse is: "You need me? I am ready." The hospital is a temple of service where the lamp never goes out. There will always be a waking ear listening for the distant cry of a mother in distress. There will always be an officer ready to go forth in the spirit of help and loving kindness. Here, in this temple of humanism, every hour is filled with a clear ideal. The mothers and the fathers know that here they have friends that they can come to and speak to, and live with. Through these mountains and forests, the Frontier Nursing Service will become a gracious presence transfiguring the individual lives. It makes an appeal that no one in the end can resist. The service draws its life from an unfailing fountain of human sympathy and love. That is what inspires the skilled and brave nurses to face the day's duty without misgiving; to feel that the least of duties is a great and holy thing and to live for all their working days in the atmosphere of creative friendship. Here, in their hours with one another and their tales of adventure, they will keep warm the fires of woman's social genius. They will always feel that, here on the frontier outposts, they are living out the true purpose of the Commonwealth—to prepare a worthy and dignified place for every child born to it.

ACT OF DEDICATION.

In all reverence, I dedicate this hospital to the service of this mountain people. The act of dedication will have consequences beyond all imagination. It will evoke responses along the many hundred miles of these mountain frontiers and among the millions of their people. The beacon lighted here to-day will find an answering flame wherever the human hearts are touched with the same divine pity. Far in the future, men and women, generation after generation, will arise to bless the name of the Frontier Nursing Service.

RADIUM TREATMENT OF PRIMARY CARCINOMA OF THE BREAST.*

BY GEOFFREY KEYNES, M.D. CAMB.,
F.R.C.S. ENG.,
ASSISTANT SURGEON, ST. BARTHOLOMEW'S HOSPITAL; LATE FIRST ASSISTANT, SURGICAL PROFESSORIAL UNIT.

(*With Illustrative Plate.*)

THE Surgical Professorial Unit at St. Bartholomew's Hospital, under the direction of Prof. G. E. Gask, was entrusted in 1922 with a supply of radium to be used under research conditions for the treatment of carcinoma of the breast. For three years this was used only for the treatment of recurrences which had appeared after operation. The results were instructive if unsatisfactory, for it was shown that a nodule of carcinoma could be made to disappear by local treatment with radium, although it hardly ever prolonged the patient's life, the disease having been already disseminated to more distant parts. This preliminary experience justified the extension of the treatment to primary carcinoma of the breast, and the first patient in this category was treated in August, 1924. Up to the end of June, 1928, 42 patients had been treated.

The technique and the principles of its application were tentative in the beginning, and it is unnecessary to describe in detail the stages through which they passed. The main directions in which they developed have been: (1) to distribute the dose in smaller units; (2) to prolong the time of exposure; (3) to increase the area treated; (4) to extend the routine treatment of the areas of lymphatic drainage until every accessible area was receiving what appeared to be an adequate dose.

Technique.

The technique used at the present time (July, 1928) is as follows:—

1. The patient is anæsthetised with gas and oxygen. It is seldom necessary to use any additional kind of anæsthetic.

2. The skin of the chest wall, axilla, and most of the neck is thoroughly cleaned with ether.

3. A series of punctured wounds are made in the skin round the site of the carcinoma with a pointed scalpel (Bard Parker blade No. 11). These punctures are about 1·5 cm. apart, and placed so that when the longest needles have been inserted the whole of the carcinoma and a considerable area surrounding it will be evenly illuminated by the radiations. Sometimes the intensity is increased by inserting the needles at two different levels in directions at right angles to one another (see diagram) so that a "grid" of needles is formed. If this greater intensity is likely to cause burning of the skin by reason of the thinness of the patient, or to cause massive sloughing of the growth by reason of its avascularity or of its being already ulcerated, only a single layer of needles is inserted.

4. Similar punctures are made for the insertion of needles into (*a*) the axilla; (*b*) beneath the pectoralis major; (*c*) above the clavicle; (*d*) below the clavicle; (*e*) over the first three or four intercostal spaces.

5. Needles of suitable length are then inserted (*a*) into the axilla with their points converging into the apex, so that the axillary glands will be illuminated by a cone of needles; (*b*) beneath the pectoralis major if there is a considerable space between the primary growth and the axilla; (*c*) deep to the superficial veins of the neck and deep cervical fascia so as to be in contact with the supraclavicular glands; (*d*) deep to the pectoral muscle on the costo-coracoid membrane; (*e*) obliquely into the intercostal spaces so as to be in contact with the parasternal or internal mammary glands.

6. Before the needles are inserted, each has a strand of salmon-gut threaded through the eye and knotted once. These are allowed to protrude from the punctures in the skin, and are knotted in bunches, so that if a needle comes out of place it will remain attached to the others, and will not be lost.

7. The skin is cleaned and the area under treatment is covered with gauze, which is secured in position by broad strips of adhesive rubber strapping. This overlaps the gauze all round, and forms an additional safeguard against the loss of needles. The whole is covered with wool and bandaged.

8. The needles are allowed to remain in position for at least a week, and sometimes for as long as ten days if the tumour is a large one. They are then removed under gas and oxygen anæsthesia. A specimen for microscopic section has been taken at the same time in every one of the present series, since it was necessary to have full proof that the tumour was a carcinoma. This was taken after irradiation rather than before in the belief that implantation of the growth in the incision was less likely to occur.

9. Whenever possible the patients were examined at monthly intervals for the first year. Thereafter the intervals might be lengthened to two or three months. Otherwise a report was obtained from the patient's doctor. The majority of the patients have been consistently kept under my personal observation.

10. A few patients were submitted after about three months to a second treatment with radium, and one patient received three applications.

Details of Apparatus.

For the adequate treatment of primary carcinoma of the breast it is advisable to have available 95 mg. of radium element. For some cases 60 or 70 mg. is enough, but for the larger tumours more is needed. The greater part of the radium, in the form of radium sulphate, should be contained in platinum needles each containing 3 mg. distributed along an active length of 4·8 cm. Experience has shown that needles of this size are convenient and give good results, though it is, of course, not essential that they should have exactly these measurements. These long needles are used for irradiating the tumour and the axillary lymph glands. A few shorter needles containing 2 mg. radium element with an active length of 3·2 cm. are needed for the supra- and infra-clavicular regions and the intercostal spaces. The platinum case of each needle should have a thickness of about 0·5 mm. The stock of needles should therefore be made up approximately as follows:—

---

* Being the basis of a communication made to the International Cancer Conference on July 19th.

Number.	Ra element content.	Active length.	
25	3 mg.	4·8 cm.	95 mg.
10	2 mg.	3·2 cm.	

A typical distribution of needles is shown in the accompanying diagram.

It is convenient to have three forms of introducer for placing the needles in position. Two of these are large forceps on the principle of the Spencer-Wells hæmostat with grooves cut in the jaws so that the needles can be gripped without damage. One holds the needles in the line of the forceps, the other holds them at right angles. A third introducer may be useful when a needle has to be placed at some distance from the skin, or when the tissues are very tough. This is made on the principle of the trocar and cannula. The trocar is made to project more than the full length of the needle beyond the cannula. When the trocar is withdrawn the needle is pushed by a stile along the cannula and into the track made for it by the trocar.

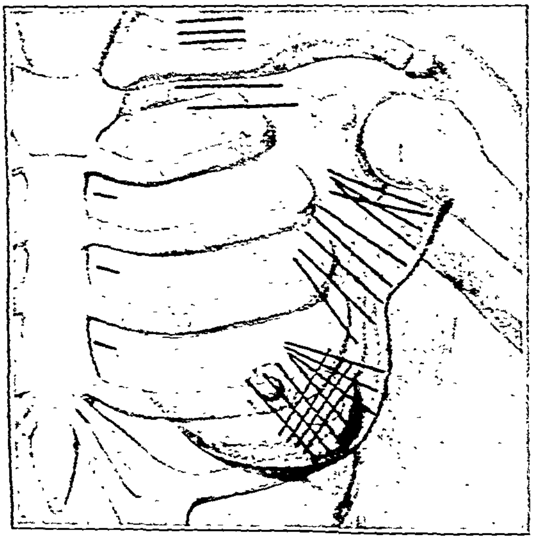

Diagram showing typical distribution of radium needles. (From a drawing by T. L. Poulton.)

Patients Treated.

When the investigation was in its initial stages it was clearly right to treat only those patients who seemed to be unsuitable for operation owing either to the position of the growth or to its being adherent to the chest wall. Later, as confidence in the treatment was engendered by the results, patients who formerly would have been submitted to operation were treated with radium, and there has been no reason to regret this. It may be pointed out, however, that on the whole the class of patient treated has been very unfavourable as regards prognosis, and this must be remembered in judging the results.

Results.

(*a*) *Primary Growth.*—The effect of irradiation upon the primary growth usually begins to be plainly seen within a fortnight of the insertion of the needles. The tumour becomes smaller and less fixed and ulceration tends to heal. In a favourable case this shrinkage is progressive until at the end of about three to four months no tumour can be detected. If at the end of four months a tumour is still present and seems to be stationary, a second treatment may be given or occasionally a local excision of the residual mass is performed. In one case a third treatment was given 18 months after the first, which resulted in the final disappearance of the tumour.

(*b*) *Lymphatic Glands.*—In the majority of the patients treated the only enlarged glands that were detected were in the axilla, the rest of the treatment given to lymphatic areas having been prophylactic. The effect on the enlarged glands has been uniformly satisfactory. Usually they have disappeared entirely, even when they had been very large, leaving no trace or only a slight thickening where they had been. So far no recurrences have taken place in any of the lymphatic areas treated prophylactically. The intercostal spaces have been irradiated only in the more recent cases.

Statistics.

Up to the end of June, 1928, 42 patients have been treated. One of these was a male. All were proved by histological examination to have carcinoma of the mammary gland. The operability was as follows: inoperable, 17; operable, 22; doubtful, 3.

Of the inoperable class six died of metastatic growths. None of these lived more than nine months after treatment, though all had shown local improvement and in two the primary growth had entirely disappeared. One (the only male) died of intercurrent disease after having been apparently cured for one year and seven months. One patient reckoned operable, though very unfavourable, died of septicæmia some weeks after local removal of the breast following two radium treatments, the carcinoma having recurred outside the area treated. Of the 34 patients that are alive, two are known to have metastases in bones and four have recurrences. In two the recurrences are in the area treated, in two outside it. Of the 28 patients that remain:—

Apparently cured	13
Tumour almost gone	1
Greatly improved	2
Improving	7
Recent (within 3 months)	5

In the cases of the 13 patients who are "apparently cured," the following times have elapsed since the first treatment:—

One, 4 years; one, 3 years 2 months; one, 2 years 2 months; one, 2 years; one, 1 year 11 months; two, 1 year 5 months; one, 11 months; one, 10 months; two, 9 months; two, 8 months.

The term "apparently cured" may be taken to mean that the primary tumour and axillary glands, if any were detected, have disappeared; in some the tissues seem to have returned to normal, but in others the destruction of the carcinoma has left some scar tissue in its place.

Of the 13 patients in this category there were: inoperable, 6; doubtful, 1; operable, 6. Among the four longest "cures" (two years and upwards), three patients were "inoperable." One of these (two years) had a large growth with a secondary mass filling the axilla. Radium was applied three times, and the successive stages in the disappearance of the tumour are shown in the photographs on the Special Plate. The patient has gained in weight and general health and has been a startling example of the results that may be obtained with radium in an apparently hopeless case. The patient who has been "cured" longest (four years) had a small growth, which was excised locally after treatment with a dose of radium now to be regarded as inadequate. She was the first patient treated and I should anticipate that excision in such a case would not now be necessary, as exemplified by the third patient treated (apparently cured three years and two months).

In order to reduce this statistical survey to its simplest terms, it will be best to eliminate the recent cases, and the single patient (although apparently cured) who died of intercurrent disease. This leaves 26 patients in whom something approaching a *result* may be claimed of not less than eight months' duration. The results are then as follows:—

Apparently cured	13*
Died of metastases	6
Alive, with metastases	2
Alive, with recurrences	2
Died following recurrences	1

* Inoperable or doubtful 7, operable 6.

A good result, therefore, has been obtained in half the patients treated, although only seven out of 26 could be regarded as operable. Of the seven operable patients, six are apparently cured. As the proportion of operable cases increases, the results may be expected to improve correspondingly. It is, perhaps, permissible to emphasise the fact that of 17 patients with inoperable or doubtfully operable growths seven are apparently cured. Some of these will no doubt succumb later on to metastatic growths in other parts of the body, but in the meantime the benefit which they have received cannot be questioned.

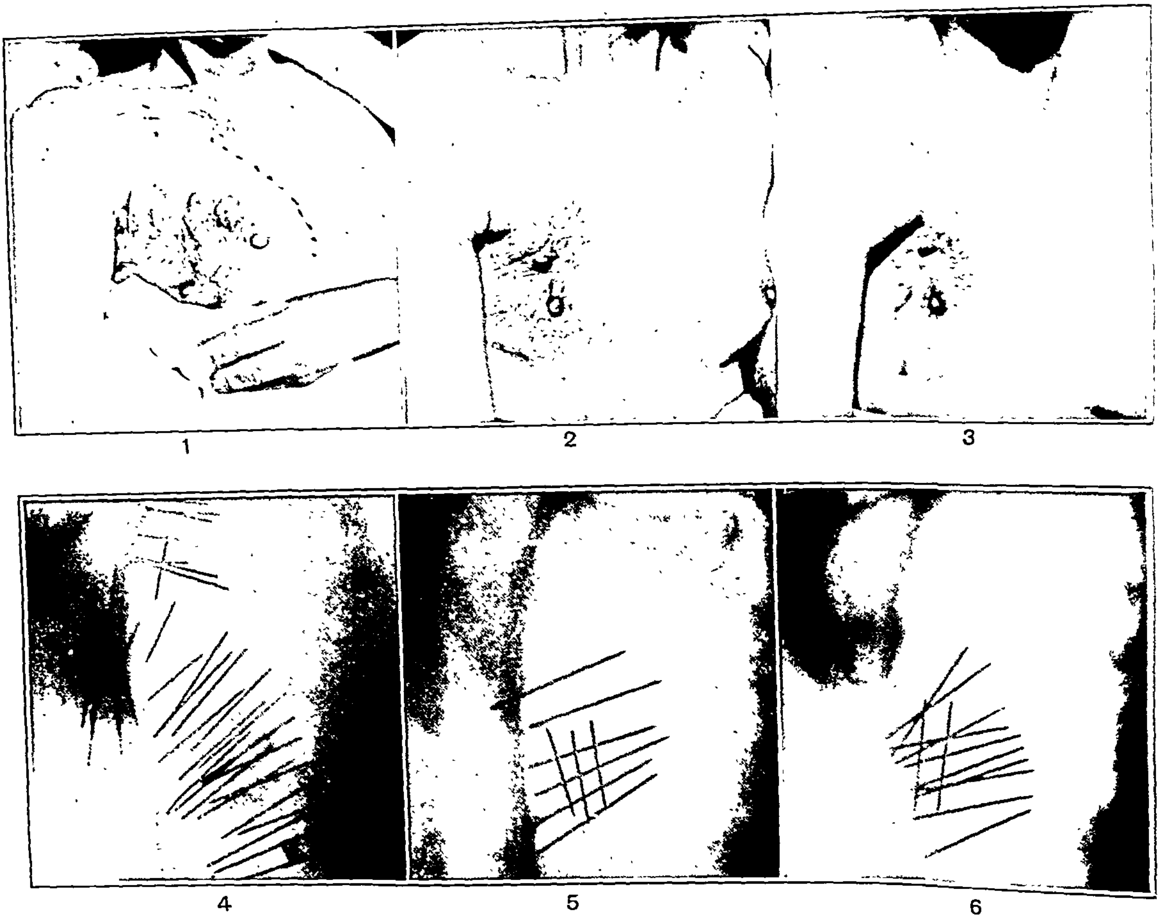
Histological Evidence.

As already stated, histological evidence of the nature of the growth has been obtained in every case. This was simply in order to prove that carcinoma was present, and only a very small specimen was taken

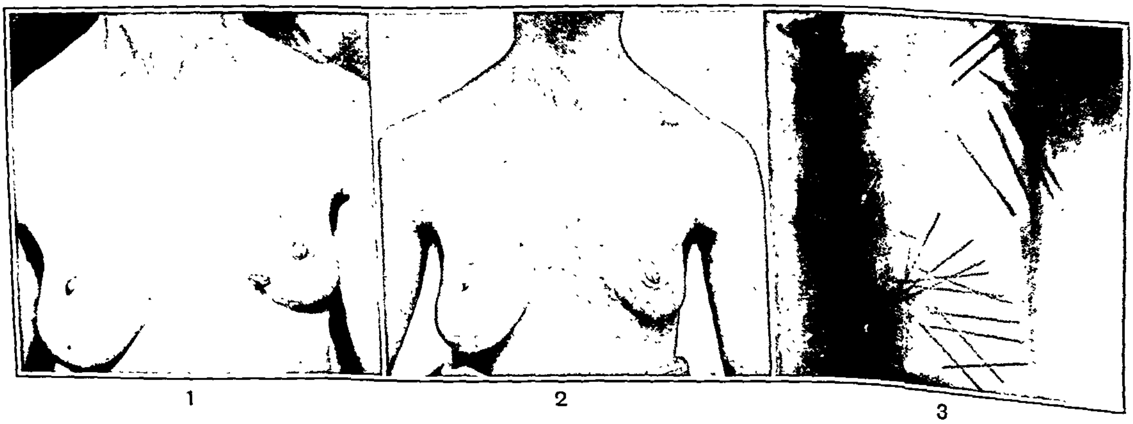
TABLE GIVING RESULTS OF RADIUM TREATMENT OF PRIMARY CARCINOMA OF THE BREAST.

Cases 10, 24, and 27 are Illustrated on the Special Plate.

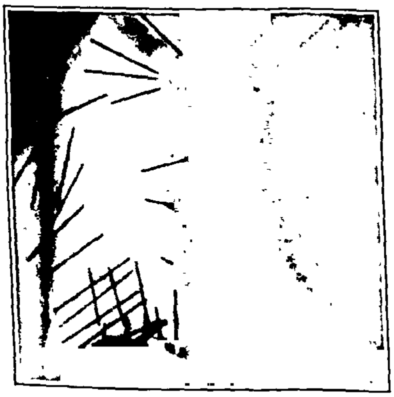
No.	Date of (first) treatment.	Type of case.	Axillary gland.	Treatment.	Result.
1	August 1st, 1924.	Ulcerated; scirrhous. Inoperable.	−	Radium (3) and excision of scar.	Apparent cure 3 years 11 months.
2	Jan. 29th, 1925.	Contracting; scirrhous. Inoperable.	−	Radium (2) and excision of scar.	Apparent cure 3 years. Recurrence in scar 3 years 2 months.
3	May 5th, 1925.	"	+	Radium only.	Apparent cure 3 years 2 months.
4	May 1st, 1925.	Massive growth. Inoperable.	−	Radium and removal of breast.	Local improvement. Died of metastases 8 months.
5	June 11th, 1925.	"	+	Radium and deep X rays.	Local improvement. Died of metastases 2 months.
6	July 10th, 1925.	Ulcerated; scirrhous. Inoperable.	+	Radium only.	Disappearance of tumour. Died of metastases 6 months.
7	August 12th, 1925.	Massive growth. Inoperable.	+	Radium only (2).	Local improvement. Died of metastases 9 months.
8	March 23rd, 1926.	Scirrhous. Operable.	−	Radium only.	Apparent cure 1 year 7 months. Died of abdominal tuberculosis.
9	May 18th, 1926.	Small growth. Operable.	−	Radium and excision of scar.	Apparent cure 2 years 2 months.
10	July 13th, 1926.	Massive growth. Inoperable.	+ +	Radium only (3).	Apparent cure 2 years.
11	August 6th, 1926.	Contracting; scirrhous. Inoperable.	−	Radium only.	Apparent cure 1 year 11 months.
12	Nov. 19th, 1926.	"	+	"	Recurrence beyond area treated 1 year 7 months.
13	Dec. 21st, 1926.	Contracting; scirrhous. Operable.	+	Radium (2) and local excision.	Death from septicæmia after excision 1 year 3 months.
14	Feb. 10th, 1927.	Massive growth. Inoperable.	−	"	Apparently cured 1 year 5 months.
15	Feb. 17th, 1927.	Ulcerated; scirrhous. Operable.	+	Radium only.	Apparently cured 1 year 5 months.
16	April 14th, 1927.	Massive growth. Operable.	+	Radium only (2).	Disappearance of tumour. Recurrence in pectoralis muscle 11 months.
17	May 20th, 1927.	Ulcerated; scirrhous. Inoperable.	+	Radium only.	Died in infirmary 9 months.
18	June 18th, 1927.	Massive growth. Operable.	+ +	Radium only (2).	Great local improvement. Died with metastases 9 months.
19	August 2nd, 1927.	Contracting; scirrhous. ? operable. Mass in axilla.	+ +	Radium only.	Apparently cured 11 months.
20	August 9th, 1927.	Scirrhous. Inoperable.	+	Radium only (2).	Recurrence outside area treated. Original tumour disappeared 11 months.
21	Sept. 20th, 1927.	Ulcerated; scirrhous. Operable.	−	Radium and excision of scar.	No recurrence 10 months.
22	Oct. 25th, 1927.	Small growth. Operable.	−	Radium only.	Disappearance of tumour 9 months.
23	Oct. 25th, 1927.		−	"	"
24	Nov. 4th, 1927.	Ulcerated; scirrhous. Inoperable.	+	"	Disappearance of tumour 8 months.
25	Nov. 30th, 1927.	Massive growth and mass in axilla. ? operable.	+ +	"	Not seen again. Has metastases in bones.
26	Dec. 16th, 1927.	Medium growth. Operable.	−	Radium only (2).	Disappearance of tumour 8 months.
27	Dec. 16th, 1927.	Ulcerated; scirrhous. Inoperable.	+	Radium only.	Healed. Tumour almost gone 8 months.
28	Jan. 6th, 1928.	Small growth; large masses in axilla. Inoperable.	+ + +	"	Tumour gone. Axillary glands much smaller. Metastases in spine 6 months.
29	Feb. 10th, 1928.	Massive growth and skin nodules. Inoperable.	+ +	X ray treatment, Ovariotomy, radium.	Improving 5 months.
30	Feb. 17th, 1928.	Medium growth. Operable.	−	Radium only.	Disappearance of tumour 5 months.
31	March 30th, 1928.	Massive growth. Operable.	−	"	Improving 4 months.
32	April 18th, 1928.	Medium growth. Operable.	+	"	"
33	April 20th, 1928.	Medium growth. Nipple ulcerating. Operable.	+	"	"
34	April 27th, 1928.	Massive growth. ? operable.	+	"	Improving 3 months.
35	April 27th, 1928.	Massive growth. Operable.	−	"	"
36	May 11th, 1928.	Ulcerated; scirrhous. Operable.	−	"	Improving 2 months.
37	May 18th, 1928.	Small growth. Operable.	+	"	"
38	June 1st, 1928.	Massive growth. Operable.	−	"	Improving 1 month.
39	June 8th, 1928.	"	−	"	"
40	June 8th, 1928.	Adherent growth. ? operable.	−	"	"
41	June 22nd, 1928.	Massive growth; ulcerated. Inoperable.	+	"	"
42	June 22nd, 1928.	Medium growth. Operable.	+	"	"



B



C



A. Case 10, inoperable carcinoma, apparently cured, in three stages: (1) 23.vii.1926, shortly after first insertion of radium; (2) 2.v.1927, before second insertion; (3) 3.vii.1928, six months after third insertion; (4), (5), (6) showing the three stages in the insertion of radium, on 14.vii.1926, 6.v.1927, and 19.i.1928, respectively.

B. Case 24, scirrhous carcinoma, fixed to chest wall, apparently cured: (1) 3.xi.1927, before treatment; (2) 13.ii.1928, four months after insertion of radium, no tumour remains; (3) 4.xi.1927, showing distribution of radium.

C. Case 27, insertion of radium 16.xii.1927, showing distribution of needles.

from the most superficial part of the growth. Knowing how much the histological appearance of a carcinoma varies in different parts of the tumour, I have not thought it worth while to make any attempt to correlate the results with the morphological type as seen in the specimens removed.

If the response to irradiation seemed to be satisfactory, no surgical operation was performed. In a few instances excision of the area treated was carried out. In the two patients first treated, although great improvement had resulted, the area treated was excised in order to obtain information. Both specimens were found still to contain some carcinoma cells, but both had received what I should now regard as an inadequate dose. In spite of this, one of the patients is still quite well after the lapse of nearly four years. The other has recurrences. In a patient treated somewhat later in the series (No. 4), a massive growth was excised five and a half months after treatment of its deep surface with radium. Sections of the irradiated surface of the growth showed that very few carcinoma cells remained in this part, though there was more carcinoma still active at a greater distance from the radium. The tissues undoubtedly protect those cells which are on that side of the tumour most distant from the radium, and it is not always possible to expose every cell to a lethal dose. This screening effect was interestingly shown in a patient who had a massive inoperable growth with discoloured bosses on the skin surface (No. 14). After two radium treatments the bosses had disappeared and the whole tumour was greatly reduced in size. There was, however, a residual mass after nine months which I thought it was wise to excise. Cross-sections through the specimen showed that it consisted almost entirely of fibrous connective tissue from which all evidence of carcinoma had disappeared, *except* for a few cells immediately under the epidermis. These cells were not normal in appearance and perhaps might have disappeared later; in any case the excision has proved satisfactory, and the patient is quite well after one year and five months. A similar residual lump excised from another patient, one year and four months after radium treatment, was found to consist of fibrous connective tissue only and no trace of carcinoma could be discovered.

Local excision has been called for in comparatively few patients, and the histological evidence is necessarily incomplete. It has, however, served to demonstrate both the partial and complete destruction of a carcinomatous growth by radium.

Advantages of Radium Treatment.

The insertion of radium needles is a trivial operation compared with Halstead's operation, and can usually be done under gas and oxygen anæsthesia. The mortality-rate should be nil. In a favourable case an apparent cure can be effected without any mutilation whatever. The lymphatic drainage can be dealt with more extensively with radium than by dissection, since it is possible to treat effectually not only the axilla, but also the supra- and infra-clavicular regions and the intercostal spaces. In no case hitherto treated has any œdema of the arm followed the application of radium. Radium can be applied with benefit to all but the largest tumours, and an apparent cure can be effected in a considerable proportion of cases which are unsuitable for any operation.

Disadvantages of Radium Treatment.

The cost of radium is at present so high that a capital outlay of £1500 is necessary for treating one patient at a time; but the stay in hospital is usually not more than ten days, so that at least twice as many patients can be treated by radium as could be treated by operation with the same hospital accommodation in the course of a year. It seems to be impossible to avoid causing in some patients a superficial skin burn, particularly in those who are thin. This results in some discomfort for several weeks, but no permanent disability results. Occasionally a very vascular tumour has sloughed away leaving an ulcer which is slow to heal. Perhaps further experience with the regulation of the dosage may lead to avoidance of this trouble.

Conclusion.

The published statistics of the end-results of the treatment of carcinoma of the breast by operation have not been very encouraging. One of the most convincing statistical reports of recent years is that compiled by J. F. C. Braine and Grant Massie and published in the *Guy's Hospital Reports* for 1926. Of the 338 cases there traced, 54 per cent. were alive at three years after operation and only 28 per cent. were alive at five years. The average of the figures published by 23 authorities from 1896 to 1926 gives a survival-rate of 41·4 per cent. for five years. If, therefore, a method other than operation is adopted, it will not find itself in competition with any very efficient means of treatment, and the results will be bad indeed if they are worse than those of operation. Furthermore, the Guy's Hospital statistics have shown that "the average period of survival is inversely proportional to the magnitude of the operation." This statement is in a sense fallacious, since it is probably true only of the advanced cases such as are commonly seen in hospital practice; yet it is clear that operation introduces a factor adverse to the patient's interests, and it might be expected that any other treatment which is locally effective will produce better results in the end. Even if the results of alternative treatment were only as good as those of operation, an alternative which rendered removal of the breast unnecessary would obviously be preferred.

I am not aware that any treatment has yet been introduced for which the claim has been made that it is better than operation for the average case of carcinoma of the breast. In the present article I have tried to describe the results of a method of treatment with radium which seems to promise results comparable with, or even better than, those of operation. Many years must elapse before a final opinion can be expressed, but the results are sufficiently remarkable to suggest that their publication should not be any longer delayed.

Several of the patients treated were referred to the surgical unit by other members of the surgical staff at St. Bartholomew's, and to them my acknowledgments are due.

POST-OPERATIVE MASSIVE COLLAPSE.

(*With Illustrative Plate.*)

THE fact that abdominal operations may be followed by pulmonary complications has been recognised since the dawn of abdominal surgery, but despite steady advances in surgery the only tangible addition to our knowledge of the abnormal processes in the lung has been the recognition, in 1908, by William Pasteur,[1] of massive collapse. This Pasteur described as a condition in which extensive areas of lung tissue, varying in size from a large portion of one lobe to a whole lung, became quite airless, blue and obviously shrunken, and sank immediately in water. The characteristic physical signs were purely mechanical accompaniments of the loss in volume, to make up for which the chest on the affected side became retracted and immobile, and the heart and mediastinum moved towards the affected side. So vehemently did Pasteur insist that massive collapse could only be suspected in the presence of this cardiac displacement that post-operative pulmonary complications have ever since fallen into three main groups.

The first is composed of cases exhibiting the essential signs of massive collapse as described by Pasteur. The second comprises cases which were regarded as post-operative pneumonia, because cardiac displacement could not be demonstrated. The third includes a few easily recognisable complications, notably those of embolic origin.

Our investigations very early showed that post-operative pneumonia is almost a chimera and that the distinction between the first two groups is little better than a shibboleth. In other words, the vast majority of all complications are massive collapses, which may or may not be accompanied by demonstrable cardiac displacement.

We followed the convalescence of 261 patients from abdominal operations of all grades of severity, with reference to the possible occurrence of declared or latent alterations in the lungs. All the cases were nursed in a more or less fully developed Fowler position.

The X Ray Appearance.

Although the physical signs of massive collapse, whether or not accompanied by demonstrable cardiac displacement, are very characteristic, its most striking manifestations are in the radiographic films, particularly when it affects the whole of one lung. (Fig. 1.)[3] The shadow cast by the airless lung is at least as dense as that caused by a thick layer of fluid, and may even obscure the rib outlines. The cardiac and mediastinal shadows, including that of the trachea, are much displaced towards the affected side, the diaphragm is elevated, and the ribs fall together so as to assume a tiled appearance.

When one or other lower lobe is involved alone, the shadow is equally dense and occupies a triangular area which, on the left side, may be almost completely overlapped by the heart. This area always indicates by its size that the affected lower lobe is much diminished in volume and, when cardiac displacement is demonstrable clinically, the degree of migration of the mediastinum and tiling may be as extensive as when the whole lung is collapsed (Fig. 3). More often the evidence of displacement is so slight as to render clinical detection impossible, and quite frequently it is entirely absent (Fig. 5). A lateral view, however (Fig. 6), shows at once that the whole lower lobe is far more shrunken than would be suspected from an antero-posterior view, and that it is completely pushed back into the posterior costo-phrenic angle by the aerated upper lobe. For the diagnosis of massive collapse, therefore, we come to Dr. Twining's[2] suggestion that we should rely on evidence of displacement of the interlobar septum, as seen in the antero-posterior and lateral views, and not on mediastinal displacement.

The first indication of the onset of massive collapse is a mottled appearance in the lung, developing during the first 24 hours after operation (Fig. 4). We have only once watched this go on to a collapse associated with marked mediastinal and cardiac displacement, because the collapse was usually fully established at the time of the first examination, but it has occurred with great frequency in the earliest stages of those cases which do not subsequently show displacement clinically. This mottling nearly always occurs in the lower lobes only, on one or both sides, and appears to be due to areas of lobular collapse, which coalesce to form massive collapse, usually of the whole lower lobe. Nevertheless, it often clears up rapidly; this may happen in one lower lobe, while the other goes on to complete collapse in a few hours. When both lower lobes are collapsed there is usually no cardiac displacement, while if one is completely collapsed and the other merely mottled, the heart is often slightly displaced towards the side of the complete collapse. This is particularly common when the right side is the more affected, since there seems to be a general tendency for displacement to occur more readily towards this side.

When the lung becomes aerated again it sometimes fails to return at once to its normal volume (Fig. 2). Its shrunken condition is partly maintained by the mechanical conditions in the pleura, which are altered by the emphysema in the upper lobe, and partly by the effects of inflammatory changes, which may show themselves in pleural thickening (Fig. 2), and the persistence of small areas of opacity in the hilum region, presumably due to residual consolidation.

Incidence and Distribution.

The table shows the incidence of pulmonary collapse in our series. Of the six cases which fulfilled Pasteur's description by giving marked clinical evidence of cardiac displacement, one affected the whole right lung and one the whole left lung, the others being confined to the right lower lobe. The number of patients in whom this picture occurred (6 in 226, or 2·3 per cent.) gives a fairly accurate indication of its frequency, since it represents a mean between the 0·6 per cent. and the 0·2 per cent. of Scott and Culter[30] in different institutions and that of Mastic's, Spittler, and McNamee[31] of about 7 per cent. There is a general tendency in this group for the right side to be more frequently affected than the left. There is usually a higher incidence among males than among females, but this is not revealed by our figures. Of the cases which showed no cardiac displacement clinically, 11 were bilateral, 10 involved the left lower lobe, and 9 the right lower lobe. We have never seen the upper lobes affected except when the whole lung has been involved.

The anæsthetic used or its method of administration—in these cases usually ether by the open method or from a Pinson's bomb—do not appear to bear any relationship to the frequency of pulmonary complications and, except that very young children are rarely affected, age does not appear to be a predisposing factor, but we feel certain that they are much more common when the weather conditions are adverse.

Ætiology.

Every mechanism which could probably bring about the deflation of the lungs has been evoked, with minor modifications, by different observers, and the question still remains unsettled. Pasteur, having originally recognised massive collapse in cases of post-diphtheritic paralysis,[3] felt certain that failure of the inspiratory mechanism was the essential cause of the condition, and the observation that after abdominal operation the whole diaphragm might be immobile without any abnormality in the lungs influenced him only to the extent of stating his theory as follows:—

> "A stimulus of unknown nature arising in one half of the body arrests the distending action of the corresponding half of the diaphragm to such a pitch that the compressors of the lower lobe on that side take charge, causing it to collapse in a manner already described."

Rose Bradford[4] considered that some reflex was operative and that the retraction of the chest wall was active rather than passive. At the same time he saw obstacles in the way of accepting Pasteur's views, and believed that, with the arrest of respiration in extreme expiration, the alveolar air was not sufficiently renewed and was absorbed by the blood stream.

Briscoe,[5] after an exhaustive research into the mechanism of respiration in the erect and supine postures, formulated a theory which differed from Pasteur's only in the supposition that the diaphragm and its synergic and antagonistic muscles were in abeyance because of posture and an inflammatory lesion in the region of the crura. Scrimger,[6] satisfied that respiratory paralysis could not cause massive collapse, considered that *some* reflex mechanism brought about a spasm of the bronchioles which was followed by absorption of the alveolar air. Scott[7] favoured a similar mechanism but preferred to believe that the reflex acted on the vessels in the bronchiole wall, which became so dilated as to obstruct the lumen. Sante,[8] who also considered that the primary cause was a reflex one, thought that it might act by causing paralysis of the bronchiole wall so that it collapsed, its walls being then held in apposition by secretions. Elliott and Dingley[9] also failed to produce collapse of the lung by complete destruction of the respiratory mechanism, and considered that it came about because of the pure accumulation of secretion in the bronchial tree. This theory has received the support of Jackson and Lee,[10] Hearn and Clerf,[11] and several other observers on purely clinical grounds.

Massive collapse occurs in debilitated children and in people suffering from bronchitis, also after severe injury of the trunk without fracture of the ribs; in portal pyæmia [1]; after thyroidectomy [12]; in cases of pneumonia elsewhere in the lung[1 13]; after gunshot wounds in the chest, abdomen and buttocks.[4 11 15 16]

* Cases with displacement conforming to Pasteur's description.
† Cases without demonstrable displacement.

It has been recorded in a case of anterior poliomyelitis[17]; in one of infective meningitis,[18] with pulmonary tuberculosis[19] following high transverse lesions of the spinal cord[5]; and in association with obvious occlusion of the bronchi by tumours, aneurysms, and foreign bodies. It seems, therefore, at the outset that any factor such as the administration of a general anæsthetic, interference with the abdominal contents or parietes, and prolonged rest in one position, which are constantly present in post-operative cases but in the absence of each and all of which massive collapse is known to have occurred, can at most only be important as contributory to some definite cause which is common to all cases.

Although Schroeder and Green[20] reported that massive collapse followed destruction of the phrenic nerves in rabbits, all other attempts to find experimental support for the hypothesis of paralytic origin have yielded absolutely negative results. Crymbles' case (No. 15) in which, after paralysis of all the intercostal muscles and the right side of the diaphragm, the aeration of the lungs was perfectly maintained by the left diaphragm alone adds further confirmation to the experimental evidence. Indeed, all the signs of massive collapse—i.e., retraction of the chest wall and displacement of the mediastinum—testify eloquently to an increase in negative pressure on the affected side which could hardly be brought about by paralysis of the very mechanism which, when it is functioning normally, helps to maintain that pressure.

Similarly, save for an experiment in which Carlson[23] produced contractions and expansion of an extremely rudimentary lung of amphibians by stimulating the intestine and peripheral nerves, there is complete lack of corroboration for the reflex factor suggested in the theories of Bradford, Scott, Scrimger, and Sante.

We ourselves are convinced that the one determining cause is obstruction of the bronchial tree. Our opinion is endorsed by the fact that, long before collapse was recognised as a clinical entity, Mendlesohn,[24] Traube,[25] and Lictheim[26] could always produce collapse of the lung by obstructing the bronchi, and that much more recently their findings have been thoroughly substantiated by Coryllos and Birnbaum. Experimentally it is quite certain that the complete occlusion of a bronchus is always followed by collapse of the lung supplied by that bronchus, because the entrapped air is absorbed by the blood. Nor is there any lack of clinical evidence in support of this theory, for many cases have been reported in which the lung collapsed because of definite obstruction of the bronchi by the foreign body, tuberculous mass, or neoplasm. In post-operative cases Jackson and Lee, Hearn and Clerf, and Harrington[27] have been able to watch the very rapid re-expansion of the lung which followed bronchoscopic removal of thick secretions.

Predisposing Causes in Post-operative Cases.

First among these is the hypersecretion caused by the administration of a general anæsthetic, or the hypersecretion of the pulmonary or cardiac condition which contra-indicated an anæsthetic. This hypersecretion is more marked in males than in females, possibly because the respiratory passages of the former are in a constant state of mild irritation from smoking. This fact may play some part in the relatively high incidence of complications in men. Secondly, the position in which abdominal patients are usually nursed tends to the gravitation of these secretions into the bronchi of the lower lobes, which are alone affected by massive collapse except when one whole lung is involved. The third predisposing cause is interference with the expulsive mechanism either by voluntary suppression or by the excessive use of morphia. In either case the cough reflex, which has been aptly called by Jackson "the watch dog of the lungs," ceases to be excited and secretions accumulate. An incision in the upper part of the abdomen undoubtedly causes more voluntary suppression than one lower down, and this probably accounts for the high incidence of complications after upper incisions. The fact that women are costal rather than abdominal breathers and probably use the costal musculature in expulsion may be a still further explanation of the smaller incidence in the female.

An important question is how much deflation can be brought about by posture and by voluntary inhibition of the respiratory movements. Briscoe, and more recently his pupil,[29] Livingstone, have demonstrated that the supine position is associated with a very marked reduction in the vital capacity of the chest, an alteration which, of course, occurs in all patients recovering from operations.

When massive collapse follows a grid-iron incision or one in the lower part of the abdomen, the initial obstruction not infrequently affects the larger bronchi and, because of the small amount of deflation already present, there is a considerable amount of volume to be made up when the air is absorbed, so that the cardiac displacement tends to be extreme. With upper abdominal incisions obstructions of the larger bronchi occur with equal frequency, but because of the excessive deflation which accompanies these incisions the minute bronchioles very readily become obstructed. This causes a diffuse lobular collapse which gives to the X ray picture of the affected lobe a mottled appearance. It is possible that a lobar collapse would result from the coalescence of these lobular areas, but this is more probably due to a gradual filling of the lower lobe bronchi with the secretions which accumulate when there is no longer a head of air to expel them nor tidal air to evaporate them. Once the lower lobe is completely collapsed the upper lobe can fill the diminished pleural space without causing any displacement of the mediastinum or heart.

This theory depends to a certain extent on the results of certain attempts which we have made at prophylactic treatment, to which we shall refer to later.

Clinical Features.

The symptoms associated with the onset of massive collapse vary very widely, and cases may be described according to their severity as fulminant, moderate, or latent.

In *fulminant* or acute cases the onset is accompanied by a "collapse attack" which, although rare, is striking enough to deserve a description. A patient who may seem fairly well suddenly becomes so cyanosed, distressed, and dyspnœic that death appears imminent. At the same time his temperature and pulse-rate become very high and diaphoresis is generally profuse. At the zenith of the attack the patient adopts a very characteristic attitude, curving his body and inclining his head towards the affected side. A collapse attack does not necessarily indicate that an unusually large area is involved. We have seen it both with and without mediastinal displacement, and the subsequent course does not differ in any way from that of others.

In *moderate* cases the dyspnœa and distress are very variable but always fall far short of the urgency of a collapse attack. The lips are usually cyanosed, the temperature about 100° F., and the pulse-rate about 120. Diaphoresis is usually present.

The *latent* cases, however, show no symptoms at all, and the explanation of a temperature of 100° F. and a pulse-rate of 120 associated with slight cyanosis must always be sought at the bases of the lung.

In his review of the cases in the literature of 1927, Scott found that in 50 per cent. the onset occurred within 24 hours of operation, in 20 per cent. after 48 hours, and the remaining 30 per cent. in the intervening period. It is fairly certain, however, that in the cases described as coming on after the lapse of 48 hours it is the recognition and not the collapse that is delayed. When the access of air to the alveolar tissue of the lung is interrupted the carbon dioxide in the entrapped air is absorbed very rapidly, and is immediately followed by the oxygen. The nitrogen, however, is not fully removed for 24 hours, so that when the lung is completely airless the obstruction has already been in existence for many hours, and in some cases it seems to become established even before the effects of the anæsthetic have completely worn off.

If a typical case of massive collapse of the lungs—say that of the right lower lobe with moderate symptoms—is seen 14 hours after operation, the temperature and pulse-rate are rising, the respirations are shallow and difficult but only slightly increased in rate, and the skin is moist. The patient may want to cough, but refrains as much as possible because of the pain. At this stage the lower part of the chest is moving very little, if at all, with respiration and the immobility is especially well marked on the right side. The heart is either normally placed or displaced to the right, or else no estimate can be formed of its position. The only physical signs in front are coarse râles heard everywhere with inspiration, but the percussion note in the back, although not absolutely dull, has lost its resonance to a degree greater than that caused by mere postural deflation. The breath sounds can be heard only on deep inspiration, and the vocal fremitus and resonance are much diminished. Moist sounds are conspicuous all over the lungs and X ray examination reveals the mottled appearance of lobular collapse in the affected lobe. Some 20 hours later the acute symptoms have almost completely subsided, but the cyanosis remains and the temperature and pulse are nearing their maximum, which, unless the condition has completely resolved, they attain about 48 hours after the operation. At this time all moist sounds have disappeared from the normal area, but the retraction, immobility, and cardiac displacement are much more marked, especially when the patient lies flat on his back. The physical signs of fully developed massive collapse are present at the right base posteriorly over a small triangle which is bounded roughly by a line passing from the sixth dorsal spine to the point where the posterior axillary fold intersects the base line.

These physical signs present an ensemble which is well expressed in the term "dead lung." The percussion note is as dull as that caused by fluid and has a very similar feel, the breath sounds are entirely absent or are heard only on the deepest inspiration, and the vocal fremitus and resonance are greatly diminished. On the fourth or fifth day the temperature and pulse-rate may return to normal, and between the third and sixth days the cough, which gradually becomes more confident, produces large quantities of thick, green, muco-purulent sputum which contains many polymorphonuclear leucocytes and presents a very variable flora. Pneumococci, *Micrococcus catarrhalis*, and *Bacillus influenzæ* were the most constant in our series. The physical signs, however, are unaltered until some time after the cough has expelled the obstructing secretions, and then they take on protean characters. Occasionally the percussion note becomes resonant at once and the breath sounds vesicular but accompanied by showers of inspiratory crepitation; loud tubular breath sounds may appear with increased vocal fremitus, bronchophony and pectoriloquy, and any intermediate condition may be discovered. Not uncommonly the physical signs have a patchy distribution, presenting one set of characteristics in one place and another elsewhere. These signs may persist for many days after the obstruction is removed and the patient appears perfectly well, but the rapidity with which the lung becomes reaerated clinically and radiologically bears a very definite relationship to the duration of the obstruction as judged by the physical signs. The obstruction is usually removed before the fifth day, after which the signs of massive collapse give place to those of its complications.

Cases 1 and 2 of our series show the most rapid recovery possible: reinflation after early removal of the obstruction brought about by turning the patient very violently on to his affected side. The sputum of Case 2 gave at one stage definite evidence of the breaking-down of the lung parenchyma, and we believe that if postural drainage had not been persistently maintained this case might have had a much less favourable issue. The majority of cases, however, ran an intermediate course.

Complications and Mortality.

Collapse, although itself of interest rather than import, may become a matter of gravity because of the complications to which the collapsed lung is liable. Experimentally these inflammatory complications have been studied in dogs by Coryllos and Birnbaum. Their general conclusion was that some degree of inflammatory change seemed inevitable if the obstruction remained unrelieved for 72 hours. After this time the most frequent complication was diffuse suppuration—a real purulent pulmonitis which evidently originated from the bronchi. Less often they found a hæmorrhagic pulmonitis resembling that of influenza, or a typical broncho-pneumonia, but never lobar pneumonia. It seems likely that the violent infective changes in dogs are related to the presence of *Bacillus coli* in the mouth, but in man the muco-purulent sputum which is nearly always present in the later stages suggests that some infection does occur, and the physical signs indicate changes in the lung varying from mere congestion to broncho-pneumonia. Scott, Lee, Pasteur, Elwyn[32] and Hirschbroeck[33] all report cases in which the secondary broncho-pneumonic condition was accompanied by severe toxæmia and ended fatally, but this is rare. A thick fibrinous exudate, however, is not uncommonly found over the collapsed area post mortem. This may be secondary to the inflammatory conditions, but in the two patients in whom it came under our notice it originated from the rupture of a subpleural abscess which was in communication with the bronchial tree.

Massive collapse and its complications are probably not attended with any estimable mortality. The cases in which the resulting broncho-pneumonia proved fatal form a very small percentage, and although four of the cases in our series came to autopsy there was always some cause of death other than the pulmonary condition.

Pathology.

It seems that a true uncomplicated case has never yet come to autopsy. Microscopically the collapsed lobe is usually found as a shrunken mass crowded up against the vertebral column by the emphysematous lobe which is not affected. It is purple-red, firm, and quite airless, so that it sinks in water, and the unaffected lungs are usually emphysematous. In the areas where the inflammatory changes are not so severe as to overshadow everything else, the alveolar spaces are greatly diminished in size and the cells, although their outline remains clear, become crowded together. Because of this approximation of the alveolar walls the lung assumes such an extremely vascular appearance that Jackson and Lee speak of an angiomatous condition. The most common indication of the inflammatory changes is the filling of the smaller bronchi by fibro-purulent plugs and the presence around them of areas which are indistinguishable from broncho-pneumonia. Differences occur in the extent of these changes, but no other inflammatory condition is described.

Four of the patients in our series died and were submitted to post-mortem examination; none of them had shown cardiac displacement before death.

In the first death was due to a large empyema on the side of the massive collapse, originating from the retroperitoneal spread of an appendix abscess. The second died, seven days after the establishment of massive collapse, from streptococcal peritonitis; the right lower lobe was shrunken, firm, and airless with pus in all the small bronchi. In the third death from peritonitis occurred seven weeks after operation; during most of this time the physical signs had suggested an effusion at the left base. The lower lobe on the left side and the lower part of the upper lobe were covered with a thick fibrinous exudate, under which the lower lobe was shrunken and airless to a degree far in excess of that which could be caused by mechanical pressure. This exudate was caused by perforation of the collapsed lung over an abscess cavity about as large as a walnut in the lower part; the cavity was proved by the injection of lipiodol to be in communication with the terminal bronchus. The fourth patient died, six weeks after operation, from infective endocarditis which apparently followed an infection of the throat during convalescence. Macroscopically the appearances were almost identical with those in the previous case, the lower lobe on the left side being contracted to less than one half of the original size and covered with a layer of fibrin resulting from the rupture of a bronchiectatic abscess three days before death.

The sections in these cases had very little in common. In the second case, although the collapse had been present for only seven days, and in the third, where it had persisted for seven weeks, the inflammatory changes were well marked and, but for the macroscopic evidence of collapse, it would have been difficult to differentiate the condition from broncho-pneumonia. There were, however, areas in which the angiomatous condition described by Jackson and Lee was vividly portrayed, and others in which the alveoli were occupied by fibrinous exudate which contained practically no cells and presented an appearance strikingly similar to the descriptions given by Coryllos and Birnbaum of one type of pulmonary complications of bronchial obstruction. The sections of the fourth case, although the collapse had persisted for six weeks, showed very much less inflammatory reaction, apart from the ruptured bronchiectatic abscess. There were a few patches resembling broncho-pneumonia and others in which there was a fibrinous exudate only, but the general appearances were those of simple massive collapse with approximation of the alveolar walls and dilatation of the capillaries.

It seems, therefore, that, although the microscopic appearance of uncomplicated massive collapse is fairly characteristic, it may be completely overshadowed by secondary inflammatory changes, and that in these circumstances due attention must be given to the macroscopic shrinkage and to the absolute airlessness of the affected lung.

Diagnosis.

massive collapse. Attempts should be made to increase the aeration of the lungs by forced breathing or the administration of carbon dioxide to produce hyperpnœa, although we are somewhat sceptical of the value of this latter treatment.

Conclusions and Summary.

1. 13·7 per cent. of all abdominal operations are followed by pulmonary complications, males being more affected than females, and upper abdominal operations more than lower.
2. Pneumonia occurring after abdominal operation is extremely rare and all these complications consist of massive collapse of the lungs, which may or may not be accompanied by the cardiac displacement on which Pasteur laid such stress.
3. Massive collapse is due to obstruction of the lumen of the bronchi, followed by absorption of the contained air by the blood stream. This obstruction most often affects the larger tubes, but when the incision has been in the upper abdomen the deflation of the lower lobe is so great that the bronchioles may become primarily obstructed.
4. About one out of every six of these cases exhibits cardiac displacement, depending on the degree of deflation of the lung before the obstruction occurred.
5. The predisposing causes are the catarrh which follows an anæsthetic, the position in which the patients are nursed, and the inhibition of the cough reflex by pain or the excessive use of morphia.
6. The clinical features, complications, pathology and diagnosis of massive collapse are described.
7. Certain measures of treatment are advised, with special reference to postural drainage.

We are indebted to the honorary staff of the Ancoats Hospital whose cases form the material of this investigation; and to Mr. P. G. McEvedy, F.R.C.S., Dr. E. W. Twining, and Dr. A. E. Barclay for much helpful advice and criticism of our efforts. For the bacteriological and pathological investigations our thanks are due to Dr. Mary Leslie Smith.

[*Note.*—A complete table of the cases investigated has been prepared and may be inspected on application to the authors.

OBSERVATIONS ON THE RADIUM TREATMENT OF VESICAL CARCINOMA.*

By A. CLIFFORD MORSON, O.B.E., F.R.C.S. Eng.,
SURGEON TO ST. PETER'S HOSPITAL FOR URINARY DISEASES, LONDON.

(*With Illustrative Plate.*)

FIFTEEN years ago the study of radium therapy in this country was in its infancy, the medical profession, with few exceptions, having no knowledge of the results which had already been obtained on the Continent. Even America, so responsive to all that is new in therapeutics, had likewise lagged behind. To N. S. Finzi must be given the credit of being the first in Great Britain to use radium in any large quantity for the treatment of malignant disease. The lack of interest shown by the hospital authorities was remarkable, and it was not until the news of the disappearance of tumours, when exposed to radium irradiation, had filtered through to the general public that they were stirred from their lethargy. Then came the reaction and the demand for the rare and expensive element became an urgent problem. There followed the usual attempts of imposters to sell metal tubes which were stated to contain radium. I recall two instances, one in which a tube supposed to contain 20 mg. of the salt proved to be empty, and the other, in which the brother of a medical man, suffering from carcinoma of the stomach, had been persuaded to take, by the mouth, radium in solution, at the price of 10*s.* 6*d.* per bottle. How many bottles he purchased I know not, but the one that came into my possession contained only a coloured fluid.

My acquaintance, in 1913, with certain workers in Paris, such as Degrais, Domenici, and Becquerel, caused me to make a special study of the changes which occur in malignant tumours on exposure to radium. The findings from this investigation were incorporated in a paper read before the Section of Pathology of the Royal Society of Medicine in the spring of 1914. They entirely confirmed the work of Domenici and may be summarised as follows:—

1. The greatest effect upon a tumour when exposed to irradiation is produced by burying the tube containing radium in its substance.
2. Unless the malignant cell is destroyed at the first exposure its power of resistance is increased with each succeeding one.
3. Different types of malignant cells differ in their degrees of sensibility to irradiation.
4. The nucleus is the first part of the malignant cell to show changes.
5. The action of radium on the connective tissue cells is similar to the attempt of nature to arrest the growth of cancer through overgrowth of fibrous tissue.

The most important advance since this date in our knowledge of the changes in cells, both normal and malignant, is that made by Dr. Ronald Canti with his cinematograph. He has demonstrated that the fibroblast is not destroyed by a comparatively large dose of radium, whereas certain other normal cells are. This is a very valuable observation when we consider the relationship of these normal cells to the inhibition of the growth of malignant disease in the human body. The clinician well knows the atrophic scirrhus, and the pathologist is well aware why it is atrophic. The overgrowth of fibrous tissue in and around the tumour has terminated once and for all the activities of these malignant cells.

A. H. Drew, of the Imperial Cancer Research Fund, carried out a number of experiments upon the growth of cells outside the body, and demonstrated that a malignant tumour will take on disorderly growth in the absence of fibroblasts. If the latter cells be added to the culture of carcinomatous tissue, the spread of the mass is immediately restrained. In other words, the fibroblast is the constable of the cancer cell. The data thus collected must have an important bearing on our endeavours to eradicate cancer with the aid of radium. Even though the malignant mass cannot be caused to disappear—the ideal at which all of us aim—we know now that it is possible to reduce it to impotence by bringing the fibroblast to our aid. Radium not only fails to have a lethal effect on this connective tissue cell but, under certain conditions, seems to stimulate its reproductive powers.

---

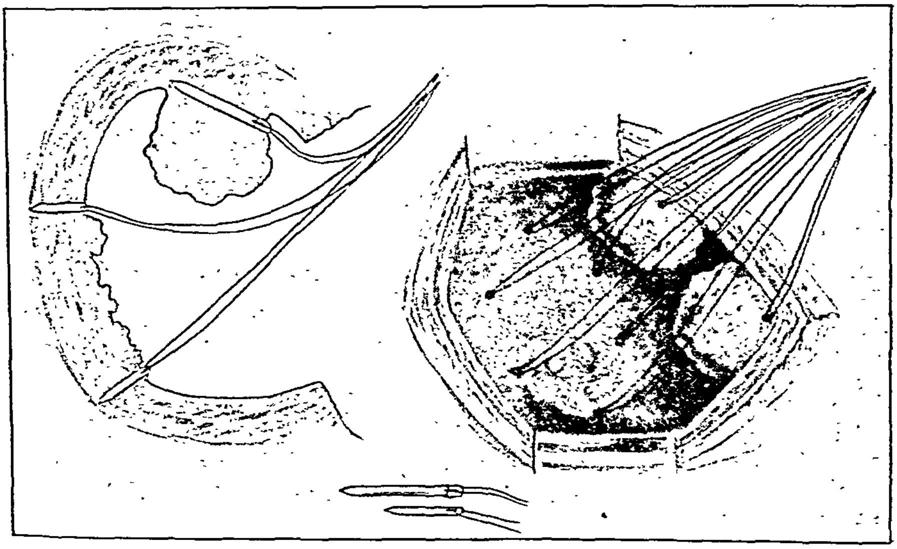
* Being a paper read before the Section of Urology of the Royal Society of Medicine, May 24th, 1928.

It is with these facts before me that I have elaborated a technique for the radium treatment of vesical carcinoma. To place one or more tubes in a haphazard way into a portion of a bladder growth, irrespective of its anatomical position and its degree of activity, is a common mistake which has brought discredit on the value of radium as a therapeutic agent. Its application cannot be carried out by any rule of thumb. The growth must be carefully defined, not only from within the bladder but also from without. The relationship of adjacent structures, such as the ureter, rectum, and large blood-vessels, should be noted and, finally, an attempt may have to be made to sweep away that most serious of all cancer complications — sepsis — before treatment is commenced. Care has to be taken that the ureter is not constricted by the overgrowth of fibrous tissue resulting from excessive irradiation in its vicinity. The same applies to the iliac vessels, in which also, on account of the sensitiveness of the lining endothelium, thrombosis is a possible complication. I have seen death take place three days after the application of a tube containing 92 mg. to within 5 mm. of the inferior vena cava. Thrombosis had extended along a considerable part of this vessel.

Operative Technique.

Access to the tumour is obtained either through the urethra or by a suprapubic cystotomy. For the transurethral application of radium an operating cystoscope is required to allow of the accurate insertion of the container into the substance of the growth. The cystoscope is then withdrawn and the radium, attached by a holder, is left in position for as long as the surgeon considers necessary. Obviously treatment with the aid of the cystoscope has its limitations, although some authorities insist that access through the urethra is the route of choice. The treatment of any bladder disease with the help of the cystoscope requires not only a well-developed visual sense, but also plenty of common sense. Is it conceivable that even the expert cystoscopist can determine accurately the extent of a cancer? When hæmorrhage or infection is severe, he will get but a glimpse of the tumour, and, moreover, the size of a tumour as seen on the mucous surface of the bladder is no guide to its depth and the width of invasion of the muscle layers. The only advantages of transurethral application are that the patient requires no anæsthetic and no incision through the bladder wall. As already stated, it is essential to define accurately the limits of the growth, and this can only be done by a suprapubic cystotomy. Under anæsthesia, either general or regional, a catheter is passed by the assistant and the bladder is washed out with an antiseptic fluid—it is my custom to use 1 in 8000 oxycyanide of mercury—and then distended. The catheter is withdrawn and the urethra compressed by a penile clamp. With the patient in the Trendelenburg position, the bladder wall is exposed, emptied of its fluid contents by trochar and cannula, incised, and retractors inserted. This allows of a thorough inspection by sight and touch of the mucous surface of the tumour. It is important to note whether the growth is of the ulcerative type or that known as the papillary carcinoma, for the method of application of the radium tubes is different in the two cases. The retractors must now be withdrawn and the fingers of one hand passed between the outside of the bladder wall and the bony pelvis, the fingers of the other hand being in contact with the lesion on its mucous surface. Such bimanual palpation will indicate the exact position of the tumour in relation to ureter, rectum, iliac vessels, and obturator nerve, also the extent of infiltration of the vesical musculature and the pelvic cellular tissue. Having determined thus the precise anatomy of the cancer and its clinical variety, careful consideration must be given to the position of insertion of each tube of radium.

FIG. 1.



Sketches to illustrate the methods of inserting radium tubes in (a) papillary carcinoma; (b) ulcerative variety of carcinoma.

Before discussing this part of the technique it is necessary to refer to the quantity of radium and the containers which have been placed at the disposal of the staff of St. Peter's Hospital by the British Empire Cancer Campaign. The total amount of radium is 200 mg. This is put up in platinum tubes, each 0·5 mm. thick, and varying in size according to the contents. There are ten tubes containing 10 mg., one tube of 50 mg., and two tubes of 25 mg. All the alpha rays, and the large majority of the beta, are cut off by the 0·5 mm. of platinum, and for all practical purposes we use nothing but gamma radiation. The radium is kept in a safe, each tube resting in a slot drilled in a mass of lead. One of the disadvantages in the use of radium in clinical research is the inability to alter the distribution of the element in the containers without considerable expense. There are times when one desires to use tubes, say, containing 5 mg. each or even less. To make such an alteration may cost £60 or £70.

Insertion of Radium Tubes in Bladder Carcinoma.

The papillary carcinoma, the cauliflower type of growth, has a pedicle which may be thick or thin, and which consists of malignant cells and vessels going to supply the main mass with blood. In such a case, insert the tubes—the amount depending on the size of the tumour—right through the pedicle, as shown in Fig. 1. The tube is left in position for 24 hours, thus ensuring destruction of the main blood-vessels and setting up an extensive fibrosis in the wall of the bladder adjacent to the tube. The latter is pushed into position by means of a special holder. The free end is threaded with silkworm-gut and the latter brought out of the bladder through the suprapubic opening and stitched to the skin. The anterior bladder wall is sewn up, except for a small opening to admit a drain and allow the silkworm-gut and radium tube to be removed without difficulty at the end of 24 hours. The drain is left in for another 24 hours.

For the ulcerative type of carcinoma the technique is modified in two respects. The centre of the tumour consists of old cells, some of which are undergoing degeneration. It is unnecessary to attack these cells, for they are suffering from senility and are therefore harmless. The cells at the margin of the growth, on the other hand, are young and in active division. The radium must therefore be concentrated at this point and in sufficient dose not only to destroy these cells but to produce a ring of fibrosis beyond the growing edge. The tubes, then, are inserted into the wall of the bladder (see Fig. 2) at the edge of the ulcer, and at sufficient distance from one another to ensure that the intervening space is bombarded with a lethal dose. Herein lies our greatest difficulty in radium therapy. That which is a lethal dose for the cancer of one patient is not necessarily lethal for the cancer of another. Until we are able by some means to determine the degree of sensitiveness of each individual's cells treatment must remain empirical. The further modification in technique consists in attacking the tumour from outside the bladder. Tubes must be buried in the cellulo-fatty tissue which is situated around the ureter and iliac vessels. They are threaded with silkworm-gut like those within the bladder, and are brought out on to the surface of the skin through the same suprapubic opening.

Radium Combined with Fixatives.

Of recent years attempts have been made to destroy cancer cells by injection into the blood stream of certain chemical substances, more particularly heavy metals in colloidal solution, colloidal selenium, and colloidal lead. So toxic, however, are these solutions that, with experience of them, it becomes increasingly difficult to believe that, to use a racing expression, they will "stay the course." On the other hand, it is conceivable that if used as activators in conjunction with radium—in other words, for the purpose of giving off secondary radiations—they may play an important part in a sustained attack upon a malignant tumour. Mottram, of the Radium Institute, has already published the results of experiments conducted with lead on these lines. If a substance is used which is fixed in the malignant cell and which, unlike lead, is non-toxic, our chances of success are improved. I believe it was Wassermann who first demonstrated that the coal-tar product eosin could become fixed in a carcinoma cell. A short time ago I was much impressed with the results of treatment of a case of carcinoma of the male breast by the injection of sodium fluorescin, followed by an X ray exposure. The investigator was Dr. Monckton Copeman. Fluorescin is a derivative of eosin, is non-toxic, is fixed in the carcinoma cell, and will give off secondary radiations. Profiting by the experience of Dr. Copeman, I injected a malignant growth of the bladder with a 2 per cent. solution of sodium fluorescin and at the same time inserted a number of tubes of radium. The result has been encouraging. It is only one case, and is therefore, from a scientific standpoint, of little importance unless the experiments are repeated over and over again.

Prognosis.

It is a striking fact, confirmed by numerous observers, that bad results are to be expected from radium irradiation where sepsis has intervened upon a malignant growth. I know of no exception to this rule. It is worse than useless in the case of vesical carcinoma. Every effort must be made with the aid of lavage to reduce the infection to a minimum. In a foul-smelling cystitis there is no better disinfectant than a weak solution of sanitas, ʒi. to the pint. Prognosis is far from hopeful, even when some success attends the attempts to eradicate sepsis.

What, then, can be regarded as a favourable factor, apart from the size of the tumour and the type of cell? It is hæmorrhage. Patients utterly exhausted from excessive bleeding and in imminent danger of losing their lives from this complication alone may be restored to a state of health which allows a breathing space for further efforts to control the disease. In severely bleeding growths, if the dosage and technique advocated in this paper be adopted—namely, a large quantity of radium with a short exposure—hæmorrhage will cease within 24 hours of the commencement of irradiation and in some cases within four hours; the suprapubic wound will heal rapidly; the general condition will steadily improve, and discharge from hospital may be expected within three weeks from the onset of treatment.

This may be termed the immediate result of radium irradiation. The remote results are as follows. In favourable cases the general condition of the patient is good, as judged by the increase in weight. Even though the urine may be quite clear, there is frequency of micturition, due to radium reaction in the mucous membrane, and slight discomfort on defæcation resulting from irritation of the rectal mucous membrane. Cystoscopy shows, at the end of three months, a curious bullous œdema of the area of mucous membrane irradiated. In other cases, more particularly the ulcerating variety and when the tumour is of large size, a mass of dead growth surrounded by a raised edge, covered by what looks like normal mucous membrane, is observed.

It is common knowledge that healing of tissues after exposure to radium irradiation may be slow. With the exception of a case treated in 1925, the reverse has happened in my cases. This is entirely due to the use of comparatively large quantities of radium with an exposure of not more than 24 hours. The report of the Medical Research Council for 1926 on the medical uses of radium records the result of the treatment of rectal cancer by 20–48 mg. of the element, left in situ for periods up to 10 days. Delay in the healing of the wounds was a noticeable feature in all cases. There is also, I submit, a grave danger of sloughing of normal tissues.

Attention has been drawn, in my article published in the *British Journal of Radiology*, to the method of dealing with the ureter, when constricted by growth, by transplanting it into a growth-free part of the bladder. With further experience I wonder whether this is necessary, provided no radium fibrosis is produced around the duct. A reference to the notes of my cases tends to support the view that relief of pressure will probably result from the absorption of dead carcinomatous tissue. Stress must be laid upon the experimental nature of the work which has been undertaken on cases treated at St. Peter's Hospital. The radium has been applied for the most part to patients already exhausted by complications and the failures of operations or diathermy. The disease has come under treatment in the inoperable stage, and in one or two cases the cancerous cachexia has been profound.

Of 12 cases treated since 1925, four have been complete failures. Of the remaining eight, one was first treated 2½ years ago. He was a man of 64 with a large ulcerative growth of the right lateral wall, spreading to the internal meatus. Repeated applications of diathermy merely seemed to increase the hæmorrhage. On admission he was collapsed from the excessive bleeding and blood transfusion had to be resorted to. The bladder was then opened and half the growth excised, the remainder being surrounded by tubes of 10 mg. of radium left in situ for 24 hours. The patient was discharged 21 days later with a healed wound and passing a clear urine. For two years he enjoyed good health, but in January of this year there was a recurrence of hæmorrhage. Cystoscopy showed a growth involving trigone and both lateral walls. 110 mg. were implanted into the growth for 24 hours, and he was discharged 21 days later with the wound healed but with cloudy urine. In March, 1928, cystoscopy showed dead growth on the right lateral wall and right half of the base of the bladder, but no hæmaturia.

Three cases treated about a year ago are alive and in fair health. One had been attending the genito-urinary department of a general hospital for three years on account of hæmorrhage, and had had numerous applications of diathermy. The growth involved the whole of the left lateral wall, including the left ureteric orifice. 200 mg. of radium were inserted for 24 hours, and he was discharged 22 days after operation with the wound healed and clear urine. This patient has put on more than one stone in weight. On March 31st cystoscopy showed a slough on the left lateral wall, with rolled-over edge. The bladder capacity is normal. There has been no hæmaturia but the urine contains a small quantity of pus.

The second case is a partial failure, in that the patient has suffered severely from radium reaction. There was much hæmaturia on admission which diathermy failed to control. 110 mg. of radium were inserted into the growth, which occupied the whole of the left lateral wall and was covered by slough and phosphates. The tubes were removed at the end of 24 hours. In March, 1928, cystoscopy showed no visible growth, but cystitis was present and the bladder was very irritable to distension. There was also rectal tenesmus and tenderness of the mucous membrane on digital examination.

The third case was a man of 63, who had been operated upon previously and treated by open diathermy for a growth of the left lateral wall. When the bladder was opened for the second time on account of hæmorrhage it was found that there was an ulcerative growth involving the left half of the internal urinary meatus and the major part of the left lateral wall. 180 mg. of radium were implanted around the margins of the growth and left in for 24 hours. The patient was discharged from hospital 21 days after operation, with the wound healed and slightly clouded urine, but no blood. On April 28th I cystoscoped this patient and found no growth, but bullous œdema of the left half of the internal meatus. His general condition was good and his weight had increased. The urine contained a small quantity of pus. He complained of irritation in the anus.

The remaining cases, four in number, have been treated within the past six months. The disease in all was in an advanced stage. Two of them have had their bladders opened at least twice for open diathermy. When I inserted radium tubes the prominent symptom had been continuous hæmorrhage. Within 24 hours in each case hæmorrhage ceased. The four of them, one a woman, are alive and in fair health.

Conclusion.

As a result of observations extending over a number of years, certain definite statements can be made. Firstly, vesical carcinoma, in our present state of knowledge, cannot be cured by radium irradiation, but a shrinkage of the tumour, even to apparent disappearance, may be expected. Secondly, severe hæmorrhage can be controlled, and therefore an improvement in the general state of health will follow.

Clinical and Laboratory Notes.

TETANUS TREATED BY INTRACISTERNAL INJECTION OF ANTITETANIC SERUM.

By Stanley E. Denyer, C.M.G., M.D. Camb.,
F.R.C.S. Eng., M.R.C.P. Lond.,
SENIOR PHYSICIAN TO THE HULL ROYAL INFIRMARY; LATE EXAMINER IN ANATOMY IN THE UNIVERSITY OF CAMBRIDGE.

In 1921 I published in The Lancet (i., 1356) a case of tetanus treated with large doses of antitetanic serum. That case was not more severe, but the period of treatment was longer than in the one here recorded. The serum in the earlier case was given intrathecally. In the present case, owing to lack of progress during intrathecal administration, the intracisternal route was used on the fifth day with almost immediate lessening of the rigidity of the jaws. The total quantity of serum used was less, being 192,000 units, as against 236,500 units given to the first patient.

A horseman, aged 21, a well-built, healthy looking man, was admitted to Hull Royal Infirmary on Feb. 22nd for stiffness of the jaws. On Feb. 19th he had noticed his jaws were stiff and thought he had neuralgia. On admission the masseter muscles were firmly contracted and he could only open his mouth a little, the greatest distance between the incisors being 0·75 cm. He complained of stiffness of the jaws, the back muscles (especially between the shoulders), both legs, especially the left, and the abdominal muscles, which were so rigid that the movements of the diaphragm were impeded. This may have been due partly to the rigidity of the diaphragm itself, as later some bronchitis developed. The source of infection was evidently a sore on the left heel, which was red and tender: the left leg was much stiffer than the right. He had other cuts on his hands and legs. These were all treated with tinctura iodi and other antiseptics. The pulse-rate was 100, the temperature 99° F., and the blood pressure 82 115. Heart, lungs, and urine showed nothing abnormal. The knee-jerks were both exaggerated and ankle-clonus was present in both feet. There was no Babinski sign. There was incoördination of both hands and slight pallor of the optic discs.

He was given large doses of antitetanic serum of high potency intrathecally, intramuscularly, and subcutaneously, for five days.

On Feb. 22nd the cerebro-spinal fluid was under increased pressure. He was put on four pints of milk in the 24 hours. On the 23rd, at 3 A.M., grs. 20 of chloral and grs. 30 of potassium bromide were given, as he was unable to sleep and complained of headache and pain in the back of the neck and between the shoulders. He had a bad night. His diet was increased by adding three eggs and 2 oz. of sugar of milk per diem, with water ad lib. to dilute the toxin. A rectal wash-out was given. The sores were treated with tinct. iod. three times daily. On the 24th rhonchi were present in the chest, owing probably to the rigidity of the diaphragm and the recti abdominis, so he was put on a mixture of ammon. carb. and vin. ipecac. His teeth were frequently attended to. Lemonade and Valentine's meat juice, one drachm in water every four hours, were given. On the 25th his pulse became weak and irregular. Natibaine ♏ 15 was given three times a day. At the same time he developed a severe attack of herpes labialis, which caused him considerable discomfort. This cleared up fairly soon with an ointment of hydr. ammon. chlor., grs. 10, ung. boric, drs. 2, ung. zinc, drs. 6. The abdomen was still very rigid, but the legs moved more freely. The rigidity of the jaws continued, and with the greatest effort he could not open his mouth more than 0·5 cm. He had no headache and was taking well five pints of milk and five eggs daily, with water, lemonade, and Valentine's meat juice, one drachm four-hourly. A third of a grain of morphine was given at night.

On Feb. 27th, as the spasm of the masseters continued and the mouth could be opened only 0·5 cm. with much difficulty, 10,000 units of serum were given intracisternally under local anæsthesia, 1 c.cm. of 2 per cent. novocaine being injected into the skin and deep tissues at the back of the neck; 10,000 units of serum were given intramuscularly at the same time. After the intracisternal injection he had some headache all night, but this disappeared in the morning. On the morning of the 28th he stated that he had no headache and said that he "felt grand this morning." Eighteen hours after this injection his mouth could be opened to 0·9 cm. and both the abdomen and legs were less rigid. Later in the day he had slight headache. The optic discs showed slightly blurred outlines. The temperature was 98·4°, the pulse-rate 110; respirations 24.

On Feb. 29th the mouth opened more easily and the herpes had improved. He felt better in himself; his legs moved easily and were not so stiff. The abdomen was less rigid and the breathing was easier, due probably to the diaphragm being less rigid. On March 2nd the diet was increased to bread crumbs and mince. He was able to open his mouth 1 cm. On the 5th his mouth opened 1·1 cm. easily. There was still some rigidity of the abdomen, but no pain. The jaws did not feel so stiff. On the 6th the legs were less rigid, but the left was still more rigid than the right. The abdominal rigidity, although less than on admission, was still quite marked; the back muscles were much softer and felt more comfortable. On the 19th he could open his mouth 2·6 cm., which is about normal for him. There was still some rigidity of the abdominal muscles: otherwise he was in good health. On the 27th the rigidity of the abdominal wall had gone and he felt very well. He was able to do work about the ward. On the 28th he was discharged.

Table of Injections of Antitetanic Serum.

Date, 1928.	Sub-cutaneous.	Intra-muscular.	Intra-thecal.	Intra-cisternal.	Total.
Feb. 22nd ..	—	10,000	20,000	—	30,000
„ 23rd ..	10,000	10,000	20,000	—	70,000
„ 24th ..	10,000	10,000	—	—	90,000
„ 25th ..	—	10,000	10,000	—	110,000
„ 26th ..	10,000	10,000	—	—	130,000
„ 27th ..	—	10,000	—	10,000	150,000
„ 28th ..	10,000	—	—	—	160,000
„ 29th ..	10,000	10,000	—	—	180,000
March 2nd ..	3,000	3,000	—	—	186,000
„ 6th ..	3,000	3,000	—	—	192,000

Pathologist's report on cerebro-spinal fluid.—Wassermann, negative. Cells, less than 1 per c.mm. Protein, 30 mg. per 100 c.cm.

The intracisternal injection seemed to have a more marked effect on the spasm of the jaws than on the other muscles, and the improvement in his general well-being was due to his being able on this account to take more nourishment, as well as to a great reduction in the toxic condition.

Technique of Cistern Puncture.

The cisterna magna lies anterior to the occipito-atlantoid ligament. Fluid is obtained at from 4·5 to 6 cm. depth; in this case it was obtained at 4·5 cm. In another case punctured a week later it was 5·6 cm. before fluid was obtained. The hair is shaved off the head at the back for about two inches. Tinct. iodi is applied and 1 c.cm. of 2 per cent. novocaine is injected in the line where the puncture is to be made. The patient is put on his left side with his head suitably flexed; a dab of tinct. iod. is smeared on the mastoid process in the external auditory meatus and glabella line. The needle, guarded to 5 cm., or more in a big patient, is inserted just above the spine of the axis, which can be felt, and is pushed in until the edge of the foramen magnum can be felt with the point, going very slowly, in order not to blunt the needle. The point is depressed and pushed carefully upward, in order to keep away from the medulla. There is usually about 2·5 cm. between the dura mater and the medulla. The needle should be pushed very slowly after feeling the edge of the foramen magnum, the stylet being frequently taken out to find if fluid is reached.

It is a good plan to rotate the needle, as it helps it to pierce the membranes with less force and thus reduces the risk of injuring the medulla.

When the cerebro-spinal fluid begins to flow 30 cm. or more are withdrawn and replaced by a rather lesser quantity of serum. The head should be kept low, using only one small pillow, and the foot of the bed raised by blocks about 6 inches high.

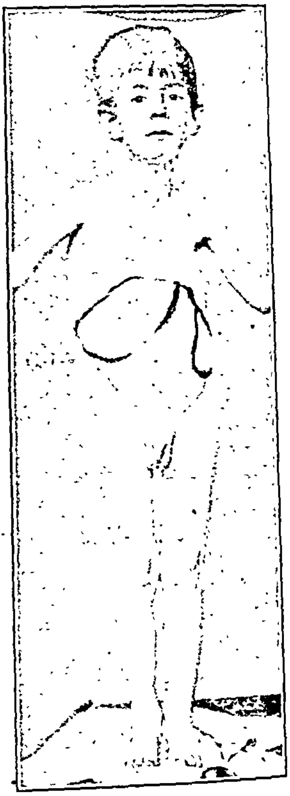
A CASE OF
RECOVERY FROM AMYLOID DISEASE.

By G. F. WALKER, M.D. LEEDS, M.R.C.P. LOND.,
LATE RESIDENT MEDICAL OFFICER, THE GENERAL INFIRMARY, LEEDS.

THE object of this account is to describe a case in which serious and advanced amyloid disease regressed completely when the septic focus was treated. Amyloid disease is rarely seen nowadays—regression appears to be outside ordinary clinical experience. Moreover, the case shows in a remarkable way how completely one lung can be thrown out of action without serious prejudice to the patient's vitality and activity.

In January, 1918, the patient, the only child of a widowed mother, and then aged 4, was admitted for a post-pneumonic empyema. Drainage by ordinary intercostal incision was established and the child did well at first. After a little while drainage became inadequate and the boy became a severe invalid with fever and wasting. Against the most urgent advice he was taken from hospital and was lost sight of by us. He was in a critical condition for many weeks; he was unable to move his limbs and had to be wheeled about in a little carriage. Again and again the wound spontaneously healed and reopened. In January, 1919, he reappeared in hospital in desperate straits. The wound was reopened and good drainage established, with marked amelioration in the condition. After some months of fair health fever and wasting returned and obvious septic absorption from a thoracic collection was taking place.

In November, 1919, further drainage by rib resection was effected, and again a marked improvement in general physique was noted. The wound healed and again broke down. A further rib resection was done with careful wound toilet, and the boy was not seen again for several months, during which time he enjoyed fair health. In January, 1920, his health began to fail again, and a serious decline took place. There was fever, wasting, and never-ending wound discharge.



The patient in May, 1920, showing deformity of chest and enlargement of liver and spleen.

By May, 1920, he was very anæmic and extremely wasted; altogether a miserably cachetic specimen. The operation site was an ugly sinus, discharging freely. The fingers were clubbed. The smooth and very considerable enlargement of the liver and the spleen (see figure) together with albuminuria made clear the diagnosis of amyloid disease.

The sinus was reopened and irrigated; there was great improvement in general health and some lessening of the discharge, but again relapse took place.

His condition was now so critical that it was thought hopeless to do anything further. After much doubt, surgical measures were again decided upon, largely on account of the recuperative power which this particular boy had shown in each preceding partial recovery phase. In October, 1920, Mr. J. F. Dobson performed an extensive thoracoplasty in several stages. He removed the posterior portions of the ribs over the wound site, taking a piece out of each rib from the third to the tenth inclusive. Very free drainage was thus provided and the chest wall was allowed to begin its collapse inwards. This collapse, which constituted the essential mode of cure in this patient, took place gradually over a period of 16 months. From February, 1921, to March, 1922, steady drainage and wall collapse were carefully tended at home and firm improvement noted in all ways. Diminution in size of the liver and spleen, with steadily lessening cachexia, was noted as early as May, 1921. In April, 1922, the wound was finally and soundly closed and the chest wall was permanently collapsed. The collapse was so great as to obliterate almost completely the left half of the thoracic cavity. Thereafter he never looked back; he began to grow rapidly and soon attained good health.

In 1926 he was a vivacious, active schoolboy, taking his place among his fellows at work and play. The liver and spleen could not be palpated, nor could any signs whatever of amyloid disease be detected. The left chest was completely stove in and there was a slight compensatory scoliosis, but there was remarkably little postural deformity visible when the boy was clothed in a loose shirt, and there was still less physical disability. No evidence of activity in the left lung could be heard, but the right lung was hypertrophic. In 1928 continued good health and welfare are reported.

I am indebted to Dr. W. H. Maxwell Telling and Mr. J. F. Dobson for permission to record this case.

AN UNUSUAL CASE OF LYMPHOGRANULOMA WITH GENERALISED METASTASES.

By B. B. YODH, M.R.C.P. LOND.,
PHYSICIAN, SIR J. J. HOSPITAL, BOMBAY;
AND
S. R. JOGLEKAR, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

THIS case is worthy of record, as it is rare for lymphogranuloma to develop general metastases and end fatally within a period of three weeks.

The patient, a Hindu male jeweller from Madras, aged 37, was admitted, on August 4th, 1927, into the medical wards of the Sir J. J. Hospital with an out-patient diagnosis of "ascites." The history was as follows:—For two months before admission the patient had suffered from gradual enlargement of the abdomen, swelling of the feet, dyspnœa and cough, especially at night. The complaint started with burning pain in the abdomen which lasted for five days only, and was followed by gradual abdominal enlargement. Fifteen years previously the patient had had gonorrhœa and a "sore" on the penis, and for the last seven years pain in the abdomen on and off, made worse by meals, but relieved about two hours afterwards without any vomiting and without taking more food. The pain was, however, never bad enough to stop him from working, and his general health was quite good all the time. Five years previously he had had for a few months intermittent fever preceded by rigors. There was no history of dysentery. He was usually constipated.

He had drunk about half a bottle of whisky per day for 20 years and used to smoke a number of "bidis" (Indian cigarettes) per day. He had, however, stopped using alcohol and tobacco since the present complaint started. Father and brothers were alive and well; mother had died of "paralysis" eight years previously.

On admission the patient was wasted, anæmic, and had orthopnœa. Temp., 98° F.; pulse-rate, 112; resp., 35. The abdomen was greatly distended, and there were signs of free fluid in the pelvis and flanks. In the epigastrium a slightly nodular lump was felt. This was dull on percussion, and the dullness was continuous with the liver dullness above and the splenic dullness on the left side. The spleen was palpable three fingers' breadth below the costal margin. The respiratory system, except for a prolonged and harsh inspiratory sound, was normal. Pain in the joints was complained of, but there was no fluid or any other abnormality in any joint. The patient had œdema over both feet, but the cardiovascular and urinary systems were normal. Except for the abdominal pain and some constipation the alimentary system was normal, the patient having a good appetite and good digestion. There was no visible or palpable enlargement of the lymph glands in any part of the body on August 4th, when the patient was first seen, or on the 6th, when the abdomen was tapped and a little blood-stained fluid was withdrawn. Examination of the cellular deposit in this fluid revealed cells resembling epithelial cells, and also a few multi-nucleated cells.

The patient was transferred to the surgical side on August 9th with a view to exploratory operation. For the first time since admission glands in the axillæ and groins were seen to be enlarged. It was decided to tap the abdomen once more before an operation was performed, and this was done on the 15th. No more than a few c.cm. of blood-stained fluid came out. However, the same kind of fluid began to ooze out from the puncture in such large quantities that the dressings were completely soaked and had to be changed every half hour. On the 16th enlarged glands in the neck were first noticed, and there was a rapid increase in the size of the axillary and groin lymph glands. This led to a suspicion of some kind of leukæmia, but blood examination showed the following result:—Red cells: total count, 4,200,000 per c.mm. White cells: total count, 7800 per c.mm. Differential (300): polymorphs, 75 per cent.; lymphocytes, 22 per cent.; eosinophiles, 1 per cent.; basophiles, nil; large hyalines, 2 per cent.; abnormal leucocytes, nil.

On August 18th a lymph gland from the axilla was removed for microscopic examination, and the abdominal puncture, through which blood-stained fluid was oozing out continuously, was closed by a small plastic operation. By this time there were big glandular lumps on both sides of the neck. The patient was going rapidly downhill, and died suddenly on the 21st.

Post-mortem Examination.

Chest: Lungs collapsed, but normal in structure. Blood-stained fluid in the pleural cavities. Mediastinal glands enlarged. Heart and the big vessels normal except for a few atheromatous patches in the aorta.

Abdomen: Blood-stained fluid in the peritoneal cavity. All abdominal lymph glands enlarged. Liver enlarged but otherwise normal in appearance and consistency. No secondary deposits. Stomach and small intestines were normal, but in the large intestine a lump about 2 cm. in diameter was seen attached to the outer wall of the ascending colon, 4 inches above the cæcum. It projected into the lumen, but the mucous membrane was not ulcerated. The rest of the large bowel was normal. Spleen was very much enlarged and adherent to the diaphragm. A large white lump, about 6 cm. in diameter, was attached to the anterior edge and gastric surface. (This was the lump felt in the epigastrium.) Kidneys were normal.

Pieces were taken from the lymph glands, the spleen, and the ascending colon. Prof. V. R. Khanolkar examined them histologically and reported as follows:—"Lymph gland: The normal structure of the gland is entirely obliterated by a uniform tissue which shows extensive proliferation of endothelial cells, lymphoid cells, numerous plasma cells, and eosinophiles. Interspersed in this tissue are found blood capillaries and a varying number of large mononuclear and multinuclear cells with homogeneous cytoplasm and vesicular nuclei, which in multinuclear cells seem to override one another. The stroma is made up of loose connective tissue, rich in fibroblasts. Spleen: The capsule is very much thickened. There is hyperplasia of connective tissue stroma, and the substance is infiltrated by the type of tissue described above in connexion with the lymph gland. Intestine: The distinction between the submucous muscular and subserous coats is lost, and the normal structure is replaced by granulation tissue of the kind described in the lymph gland. The wall of the intestine is thickened (15 mm. in section) as a result of this process.

"Remarks: The tissues show the characters of a lymphogranuloma (Hodgkin's disease)."

This case was interesting from the diagnostic point of view. The history of addiction to alcohol and the ascites suggested cirrhosis of the liver, but the presence of blood-stained fluid and the character of the cellular deposit in it was in favour of malignancy. One of us (B. B. Y.) suspected a primary carcinomatous change in a cirrhotic liver, and the other (S. R. J.) suspected a primary growth of the stomach or the transverse colon, because of the epigastric lump and the long history of abdominal pains. The sudden enlargement of the lymph glands suggested further possibilities, such as generalised tuberculosis (though there was no fever), acute lymphadenoma, acute leukæmia, or a generalised carcinomatosis. The blood picture, however, excluded leukæmias. The diagnosis was really settled by histological investigation after death.

We are indebted to Prof. R. Row and Dr. P. V. Gharpure for the help given during the pathological investigations.

Medical Societies.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A MEETING of this Association was held on June 26th, Dr. AMY SHEPPARD presiding.

Dr. LETITIA FAIRFIELD gave an address on

CHILD GUIDANCE.

She said that she had recently had the privilege of studying the methods used in America for dealing with delinquent and difficult children and had been greatly impressed by them. The idea that the chief need of the difficult child was help in adapting itself to its surroundings was not a new one, but the scheme of clinics on a large scale designed to this end dated only from 1908. At this time a group of women in America, of whom the most prominent was a Mrs. Dummer, conceived the idea that the treatment of the juvenile delinquent was unsatisfactory and unscientific. Mrs. Dummer decided to finance a clinic under Dr. W. Healy in Chicago, and he found that if the motives of the child delinquent were studied, it often became apparent that he was not abnormal or psychopathic. Without careful inquiry it was often impossible to tell whether the child or the environment was responsible for the delinquency. From the failure of the child whose bad conduct had brought it into relations with the police, Dr. Healy worked back to those of lesser degrees of maladaptation, and came to the conclusion that the development of faulty habits might be checked and impulses might be trained in the right direction if the child were studied at an earlier stage. Meanwhile, other sociological efforts were being made. Mr. Clifford Beers, who had had an acute attack of insanity in early life and had suffered harsh treatment, resolved to dedicate his life to securing more understanding treatment of the insane. A great society, the National Committee for Mental Hygiene, with branches in all the States, arose from his efforts, and here also it was found necessary to work back to early years in order to find the origin of breakdowns in later life. This work had not proceeded on purely Freudian lines, nor had the child guidance movement developed on psycho-analytical principles, though all modern psychology had absorbed something from Freud's ideas. The psycho-biological theories of which Dr. Adolf Meyer, of the Johns Hopkins Medical School, was the chief exponent, had had much influence on the child guidance movement. This conception of conduct was that it represented the reaction between personality and environment. Myer hardly recognised types of mental disease, only types of individuals reacting to different conditions. He made no sharp distinction between the normal and the abnormal, the sane and the insane. It was on these lines that American social work was developing. Dr. Fairfield proceeded to describe the organisation of the child guidance movement. It involved a preliminary inquiry into the record of the child at school and at home, and into the results of the standardised tests for mental ability. It was surprising how often the cause of the difficulty was that the child was being tried beyond its mental capacity. Sometimes an incorrigible child was merely an overlooked defective. The tests could only be evaluated, however, with reference to the child's emotional reactions. A physical examination was performed on each child and was followed by a careful study of its environment by a " psychiatric " social worker, who was trained on the lines of our C.O.S. workers, but with special instruction in psychology and in the mechanism of behaviour. Dr. Fairfield pointed out that in America less emphasis was laid on material and more on personal factors. If a social worker in this country found that a child lived in a neat house and had good meals, she reported that he had a good home, and if the child did not get on well, the inference was that it was his own wicked little fault. No account was taken of the possibility that the mother might nag at the child or quarrel with her husband, in which case the psychological atmosphere would be that of a bad home. In any home, one spoilt child might call forth revenge reactions on the part of the others. Since all these factors were reported, the American histories were fuller than ours, and this was an advantage. The most important examination of the child was the final one by the trained medical psychiatrist, who had before him the reports of all the other workers. The examination when completed usually gave clear indications for treatment for the child of pre-school age or of school age. Children who failed during the period of parental training of the simpler instincts might develop enuresis, bad habits, temper tantrums, and persistent and serious food fads. In a certain percentage of cases they were very intractable. The education of teacher and parent in their management was being undertaken in association with kindergarten and nursery schools. For children of school age a " visiting " teacher with the training of a psychiatric social worker acted as adviser to the staff on problems of discipline. She also visited the home and reported to the teacher and vice versa, acting as a liaison officer. Since these agencies were available to deal with difficult children, only the really intractable cases needed elaborate study at guidance clinics. These clinics dealt with conduct problems and also with retardation in school work. In America the child who did not advance with his class was considered a disgrace to himself and his teacher. Very often the retardation was not a question of intelligence, but of conduct; in other cases the children were naughty because they were mentally dull and were tried too hard. Dr. Fairfield explained that the guidance clinics were under voluntary bodies such as the Commonwealth Fund, or were run in connexion with the big hospitals. The Commonwealth Fund was a wealthy organisation that had financed nine demonstration clinics, which served also as training centres. They were about to start one in London and were financing it for three years. At the Johns Hopkins Hospital, Dr. Esther Richards was in charge of an excellent clinic under the general direction of Dr. Meyer. The treatment might involve a radical change in the plans for a child's life, and was especially valuable for " dependant " children who were boarded out by voluntary societies in homes that might not be suitable to the individual need without considerable adjustment. The expansion of the movement both for children and adults was remarkable. Charitable societies were beginning to run guidance clinics, also the great department stores. District nursing associations sometimes paid a psychiatric worker to advise the nurses. This expansion proved the value of guidance clinics more conclusively than any statistics.

Discussion.

Dr. **Nina Dobbie** pointed out that in England also many dependant children were boarded out in homes.

Dr. **Alice Hutchison** said that in Leytonstone an admirable clinic was being run, but that throughout this country the work was limited by lack of funds.

Dr. **H. Mackay** asked what number of children could be dealt with at any one clinic. This was relevant to the financial aspect of the work.

Dr. **Fairfield**, in reply, said that the Cleveland Clinic consisted of three doctors, three social workers, and two or three psychologists. That team could deal with 1000 cases in a year.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS.

The summer meeting of this Society was held in Edinburgh on June 8th and 9th, under the Presidency of Mr. **Wilfred Trotter**, and with a full attendance of members.

On June 8th Mr. **Norman Dott** opened the proceedings by performing an operation, at the Nursing Home at 19, Great King-street, in which he removed an osteoma from the roof of the orbit by means of an osteoplastic craniotomy.—Dr. **Logan Turner** gave an account of his work on " The Paths of Intracranial Infection," demonstrating the meningeal and vascular connexions, particularly those in relation with the nasal passages.—In the afternoon Sir E. **Sharpey-Schafer** related the results of a study of nerve section and regeneration in his own hands. This was followed by a discussion introduced by Dr. H. M. **Traquair** and Dr. A. H. H. **Sinclair** on the Relationships of Ophthalmology to Neurological Surgery, with special reference to visual field defects.—Dr. **Graham** and Mr. **Dott** showed some cases illustrating this subject.—Prof. **Edwin Bramwell** described a case of Intracranial Aneurysm, and showed a specimen.—A dinner was held the same evening at the North British Hotel.

On June 9th a demonstration of Radiograms of the Skull was given by Dr. **Woodburn Morison** and Dr. **Hope Fowler**. Dr. Fowler discussed the Radiotherapy of Intracranial Tumours, some of Mr. Dott's cases thus treated being shown.—Prof. D. P. D. **Wilkie** demonstrated a case of intracranial dermoid cyst, successfully operated on by himself, and a case of acoustic neuroma in which a cerebellar decompression operation had been carried out.—Prof. JOHN FRASER showed a case of injury to the brachial plexus, associated with a fracture of the clavicle by direct violence, and a case of elephantiasis and trophic disturbance of a lower extremity in a child affected by spina bifida.—Mr. W. W. WAGSTAFFE read a paper on the Incidence of Traumatic Epilepsy after Gunshot Wounds of the Head, and gave figures of the frequency of Jacksonian and generalised epilepsy after these injuries.—The meeting concluded with a demonstration of Various Kinds of Cranial Anomalies by Mr. D. M. GREIG, Curator to the Museum of the Royal College of Surgeons of Edinburgh, given in the hall of the College.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE eighteenth annual meeting, held from Thursday to Saturday, July 5th to 7th, in the department of Human Anatomy of Oxford University, was opened by a short address of welcome from the Master, Mr. Philip H. Adams, Reader in Ophthalmology of the University of Oxford. Dr. Leonard Hill then opened a

Symposium on the Ultra-violet Ray.

He dealt himself with the biologically active rays, their measurement and their penetration of the skin and eye, the theory of the action and immunity to rays, the comparison of sun and lamps as sources, and the action of rays as evidenced by erythema, and touched on hæmo-bactericidal power, rickets, ergosterol, vitamin D, and pigment formation. Some interesting slides of the erythema produced by ultra-violet ray were shown.

Dr. G. M. B. Dobson, F.R.S., spoke next on the effect of atmosphere, the altitude of the sun, and the presence of ozone on the transmission and the energy of ultra-violet rays, illustrating his remarks with curves and photographs.

Dr. W. J. Turrell gave his clinical experiences of the practical administration of ultra-violet rays, emphasising the importance of the regulation of dosage. The lamp he had used for 13 years was the tungsten arc.

Mr. W. R. Ackland dealt with phototherapy in the treatment of dental disease, referring especially to pyorrhœa and its relationship to ocular diseases.

Dr. N. S. Lucas related his experiences of the treatment of rickets in marmoset monkeys by ultra-violet rays, using a mercury-vapour lamp. Reaction was observed in the eyes much more rapidly than in the human subject—i.e., in one to two hours—but passed off more quickly. He considered that some ultra-violet radiation was essential for monkeys in captivity.

Mr. G. O. Hume spoke on the local application of the rays to the eye, emphasising the importance of selection of cases and dosage.

Mr. A. F. MacCallan, whilst recognising the beneficial effect of phototherapy, urged the need for a continued search for causal conditions, notably septic foci in teeth or tonsils.

Demonstrations.

In the afternoon Mr. E. E. Maddox showed an accommodation balance test, a new fixation site for the globe in intracapsular cataract extraction, and an apparatus for training amblyopia in squint on a new principle involving hand and eye.

Mr. Rayner Batten showed a collection of fundus drawings of diseases and anomalies of retinal and choroidal vessels.

Dr. Margaret Dobson showed a test for astigmatism in which the duochrome principle was applied to the Maddox "V" test.

Mr. George Young demonstrated the instruments he now uses in the operation of double sclerotomy for glaucoma which he has devised, and slides in which the effect of the operation could be seen.

Mr. W. Niccol showed slides of a carcinoma of the choroid secondary to carcinoma of the breast.

Mr. B. Cridland exhibited a test-type for children.

Annual Dinner.

At the annual dinner held in the evening in the Hall of Keble College Mr. Adams, who presided, mentioned that 18 new members had been elected during the year, the total membership being now 414, including eight hon. members. The attendance last year was 104, including a number of well-known ophthalmic surgeons from the continent and America. He regretted to have to record the loss since then through death of Prof. Felix Lagrange, a foundation member, Dr. Brownlow Riddell, Dr. W. J. Tyson, Mr. Fredk. Dale, and Mr. T. O'Kelly.

Friday morning opened with a preliminary report by Mr. Burdon Cooper on Spectroscopy of the Crystalline Lens with a lantern demonstration showing the results of the spectroscopic examination of normal and cataractous lenses. The spectrograms showed that in cataractous lenses potassium was diminished and calcium increased.

Mr. T. Harrison Butler next read a paper on Sympathetic Ophthalmia, which was discussed by Messrs. S. H. Browning, Malcolm Hepburn, H. M. Traquair, and A. W. Ormond.

Doyne Memorial Lecture.

This lecture was given by Dr. Arthur Thomson, Lees professor of human anatomy in the University of Oxford, who chose as his subject Observations on the Eyes of Birds. After reviewing the literature of the past 250 years on the pecten he described its anatomy with the aid of slides and models. He showed how the most prominent portion of this structure which projects furthest into the globe is more closely attached to the hyaloid membrane overlying it than the lateral portions. The hyaloid lying upon this black pigmented structure acts as a dark mirror and its function may reasonably be taken to be that of eliminating dazzle from the direct rays of the sun, with reflection of objects from the upper field of vision to some other part of the retina. The value of this in the case of all birds other than prey-birds would be at once seen. The latter hovering with back to the sun and in the region of dazzle as far as the ground bird is concerned is in a position of vantage. If, however, the bridge of the pecten is a dark mirror, reflecting the image of the prey-bird, nature has provided the ground-bird with a suitable means of defence.

At the conclusion of the lecture Prof. Thomson was presented with the Doyne memorial medal for the year.

Mr. G. R. de Beer, lecturer in comparative and experimental embryology in the University of Oxford, then gave a paper embodying original work on the development of the vertebrate eye.

In the afternoon a visit was paid to the Morris Motor Works.

On Saturday morning the session opened with a paper by Lieut.-Colonel Henry Smith, on the Nutrition of the Lens and Vitreous. On analogy with the uterus with its rhythmic contractions as a means of maintaining circulation and thereby nutrition, he suggested that a sluice-like action of the ciliary muscle of the eye occurred whereby the canal of Schlemm and neighbouring spaces were opened and relaxed and so aided the circulation of the aqueous humour.

Clinical Cases.

Reports were given of the following cases:—

Miss Ida Mann: "A Congenital Abnormality of the Retina."

Mr. John Rowan: "A Case of Gliomata of the Retina." Both eyes were removed for gliomata at 1 year and 5 months; no recurrence after over three and a half years.

Mr. George Young: "A Case for Diagnosis." Enuresis up to the age of 17, which disappeared after correction of some hypermetropic astigmatism.

Mr. J. A. Ross: "Keratitis with Intranasal Causation." Keratitis of 15 years' standing cured after treatment of an anterior ethmoiditis.

Mr. C. G. Russ Wood: "Case of Mikulicz's Disease with Complications."

Mr. W. Niccol: "A Case of Recurring Membranous Conjunctivitis."

Miss Marion Gilchrist: "A Case of Keratitis Marginalis Profunda occurring in Both Eyes."

In addition to the scientific exhibits a commercial museum was on view in which 14 well-known makers of ophthalmic instruments showed their latest forms of apparatus.

The attendance at the Congress was well over a hundred; the absence of members from abroad is to be explained by the fact that the International Congress of Ophthalmology falls next year at Amsterdam.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

A MEETING of this Society was held in the University New Buildings, Edinburgh, on July 13th and 14th, Prof. J. LORRAIN SMITH, Prof. T. J. MACKIE, and Dr. A. G. MCKENDRICK in the chair.

W. M. CROFTON (Dublin) described a pleomorphic microbe which he had isolated from vaccine lymph and small-pox, and IVY MACKENZIE (Glasgow) dealt with another organism, obtained on many occasions from the cerebro-spinal fluid of an obscure nervous case, which appeared as threads cocci or diphtheroid bacilli, Gram-positive and Gram-negative, under different conditions.—L. S. P. DAVIDSON (Edinburgh) had found a great excess of *B. welchii*, *B. coli*, and streptococci in the stomach contents and fæces of cases of pernicious anæmia; the degree of sepsis was not altered when the anæmia was cured with a liver diet. No special type of organism could be identified as associated with the disease.—J. CRUICKSHANK (Aberdeen) pointed out that the Voges-Proskauer reaction (due to the production of acetylmethylcarbinol by certain intestinal bacilli) was obtained more quickly and certainly if glucose in the medium was replaced by cane-sugar.—D. P. D. WILKIE (Edinburgh) in cases of cholecystitis found streptococci much more frequently in the cystic lymph gland than in the contents or wall of the gall-bladder; the cocci thus obtained when repeatedly inoculated into rabbits produced a chronic cholecystitis and gall-stones.—H. J. PARISH and C. C. OKELL (London) retested 533 Schick-negative children one to seven years later and found 1·1 per cent. positive; of 440 children who had been made Schick-negative by immunisation 5 per cent. proved to have become positive after about the same length of time.—J. A. ARKWRIGHT (London) discussed the parallelism between acid and serum agglutinations.—C. H. BROWNING and E. M. DUNLOP (Glasgow) dealt with the influence of the amount of alcohol in the mixtures on the Wassermann reaction.—E. M. DUNLOP (Glasgow) described his observations on the fixation of complement by typhoid and other bacilli. and T. J. MACKIE (Edinburgh) discussed the action of normal serum and some non-antigenic substances.—J. GORDON and A. WORMALL (Leeds) had investigated the relationship between the bactericidal action of normal serum and its content in hæmolytic complement.—D. F. CAPPELL (Glasgow) found that filling up the reticulo-endothelial cells with, e.g., trypan blue had no influence one way or the other on the susceptibility of mice to pneumococci.—J. L. OWEN (Leith) argued that the present methods of determining blood groups were unsatisfactory owing to variations in titre and the presence of the third (Cγ) component, which might occur without A or B. Direct cross-testing between donor and recipient was the only safe procedure.—G. M. FINDLAY (London) explained the determination of bacteria to a locus of tissue injury by showing that injections of histamine had the same effect.—C. PRICE-JONES (London) had measured the red cells in a number of cases of pernicious anæmia before and after treatment with liver, and showed that the cure of the anæmia did not remove the excess of abnormally large cells, though it usually brought the diameter curve nearer the normal shape and position.—C. J. POLSON (Manchester) described his experiments on the disposal of dialysed iron injected intravenously by the reticulo-endothelial system.—C. DIVER, F. M. TURNER, and A. E. BOYCOTT (London) gave an account of the inheritance of reversed symmetry and the non-inheritance of monstrous shell-shapes in a mollusc.—J. LORRAIN SMITH and T. RETTIE (Edinburgh) studied the intestinal absorption of fat in the guinea-pig and suggested that the mucosa stores fat in much the same way as connective tissue.—W. E. GYE and W. J. PURDY (London) described further experiments on the filtrability and stability of extracts of Rous tumours, and pointed out the parallelism between the action of various agents on the effective agent in the tumour and on the virus of pleuro-pneumonia.—A. L. TAYLOR and M. J. STEWART (Leeds) described six single and multiple plasma-cell myelomata; the clinical course is relatively benign.—H. G. CRABTREE (London) had measured the carbohydrate metabolism of various pathological epithelial overgrowths and found that lesions such as those of fowl-pox showed the respiratory features supposed by Warburg to be characteristic of malignant tumours.—J. S. YOUNG (Leeds) showed that hyperplasia of the pleural endothelium and of the nearby alveolar epithelium could be produced by injecting strong solutions of sodium chloride into the pleural sac and more readily by calcium strontium and especially aluminium salts.—D. M. MORISON (Edinburgh) tied the ureter and introduced dyes into the kidney pelvis; they were absorbed first by the lymphatics and afterwards passed up the tubules as far as the second convoluted tubule.—T. SHENNAN (Aberdeen) defended the proposition that external mechanical violence often plays a part in producing partial or complete tears of the healthy aorta.—D. F. CAPPELL (Glasgow) showed three instances of vertebral chordoma, and W. SUSMAN (Manchester) an obscure, probably neurogenic, sacral tumour. T. D. HAMILTON and N. M. DOTT (Edinburgh) correlated the cytological characters of cerebral gliomata with their clinical history. G. MCCALLUM (Edinburgh) described an ovarian teratoma in which carcinoma and chorion-epithelioma developed.—A. W. GREENWOOD, C. F. W. ILLINGWORTH, and R. D. MACKENZIE (Edinburgh) showed a new transplantable fowl tumour; C. F. W. ILLINGWORTH a series of specimens of cholesterosis of the gall-bladder and the mechanism of formation of cholesterol stones on a pigment nucleus. W. G. BARNARD (London) showed giant-cells in organising broncho-pneumonia, queer bodies in granulomata in a rabbit's lung, and a mass of fungi crowded with tubercle bacilli in a tuberculous cavity in the lung.—W. Q. WOOD and D. P. D. WILKIE (Edinburgh) had an exhibit of carcinoma of rectum.—E. M. DUNLOP (Glasgow) showed two unusual organisms from urinary infections, D. F. CAPPELL (Glasgow) a tumour of pleura with glomerular metastases, W. F. HARVEY (Edinburgh) pathological conditions associated with heat-stroke and a series of large microscopic sections. D. G. S. MCLACHLAN (Edinburgh) demonstrated the formation of "clubs" round masses of tubercle bacilli injected intravenously.—T. SHENNAN (Aberdeen) showed how any ordinary photograph can have the parts required marked in with Indian ink and then the rest be bleached with iodine and acid hypo, leaving a black-and-white line and dot drawing.

STOCK EXCHANGE DERBY FUND.—From the Stock Exchange Mutual Subscription Fund, popularly known as "the Stock Exchange Derby Sweep," a sum of £50,530 has been allocated to a long list of charities, chiefly hospitals, being rather more than 10 per cent. of the total amount received.

nd Notices of Books.

RS.

J. NORMAN, M.B., D.P.H. Edin.,
rintendent, Camberwell House,
urer on Mental Diseases, West-
tal Medical School. Edinburgh:
gstone. 1928. Pp. 463. 14*s*.

cho-analysis in the treatment
re is much to be said for this
e this handbook is likely to
become popular with medical students, whose education in these matters requires to be undertaken with great care.

In the chapter on mental disorders associated with bodily diseases, it is surprising to find no mention of heart disease; disseminated sclerosis is ignored in the chapters devoted to mental disorders associated with organic disease of the nervous system. The urgency of early recognition of general paralysis might well be insisted upon in a future edition. The results of modern therapy are sufficiently impressive to make the early diagnosis of the disease a matter of great moment. Failure on the part of the practitioner to insist on venepuncture and lumbar puncture as soon as there can be any suspicion of general paralysis may well come to be regarded as negligence by the public. Apart from these small points, the account of the mental disorders is one of the best presentations available for the busy student of medicine.

The section on psychology reflects the author's leaning towards the physiogenic school of thought. He is anxious to correlate disordered conduct with disordered neurones. Consequently, the school which regards the wish as the unit of mind is not very adequately represented in the text. Here, again, it is better that the student should be told nothing at all, than be given inaccurate and distorted accounts of the psychological concepts which have resulted from the work of Freud. Unique among text-books is the charming chapter on "clinical examples in life and literature." From the enormities of some of the Cæsars to the adventures of Mr. Preemby in "Christina Alberta's Father," Dr. Norman gives us a glimpse of a veritable gallery of insane portraiture drawn from history and literature. The reading of this chapter provides a great stimulus to the interest of a casual reader, and is likely to promote interest in mental disease among both students and practitioners. Finally, there are adequate chapters on mental deficiency, on pathology and treatment, and on the legal relationships of insanity. The bibliography at the end of the book reflects the wide reading of the author, and is a most useful appendage to the volume.

This book can be commended especially to the medical student. It contains a great deal of matter in a small space, and is admirably printed and illustrated. Dr. Norman is to be congratulated on his success in the apparently impossible task of writing a short text-book on mental diseases which will give the veteran fresh ideas and new outlooks, and will provide the recruit with a sound grounding in psychiatry.

TEXT-BOOK OF PATHOLOGY.

Lehrbuch der Allgemeinen Pathologie und der Pathologischen Anatomie. By Prof. H. RIBBERT. New edition by Dr. CARL STERNBERG, Professor of Pathological Anatomy, University of Vienna. Leipzig: F. C. W. Vogel. 1928. M 45.

Ribbert's well-tried text-book of pathology has been happily reinspired by Prof. Carl Sternberg. The volume is up to date and accurate. It is intended for students, and does not take the place of such works as that of Aschoff, though the chapter on fat necrosis seems to show a certain coincidence of matter and phrasing—perhaps inevitable in the circumstances in the two volumes. The 700 illustrations include a photograph of a female corpse burnt to death which seems redundant. Monstrous twins are stressed too much in a book which dismisses blood diseases and malaria rather summarily. The treatment of arterial diseases is particularly good. The volume will not tell the specialist in pathology much that he did not know, but it covers with excellent judgment the whole field of morbid anatomy, and to a less degree morbid histology.

FOOD INFECTIONS AND FOOD INTOXICATIONS.

By S. R. DAMON, A.M., Ph.D., Associate Professor of Bacteriology, The Johns Hopkins University. London: Baillière, Tindall and Cox. 1928. Pp. 266. 18*s*.

FOOD may be poisonous to man because of the presence of inorganic chemicals, organic poisons, pathogenic bacteria, or larger parasites. Classification is not simple, however, because some pathogenic bacteria, such as *B. botulinus*, do not actually invade the human body but cause disease by reason of the exo-toxin they produce when growing in food substances. This exo-toxin acts like an organic chemical poison, and the disease botulism resembles an intoxication more than an infection. Dr. Damon has attempted such a logical classification and divided his book into three parts, dealing respectively with infections from food, intoxication from food, and parasitic infections acquired through food. This makes a convenient grouping for Salmonella infections, tuberculosis, undulant fever, and actinomycosis because these are all true infections, but, though logical, it savours of pedantry to divorce botulism from other microbic diseases, and make it keep company with potato poisoning, the poisonous fishes, and toadstools under the heading of *intoxications*. It might be expected also that the author should have found a place for the inorganic poisons, arsenic, lead, copper, and zinc, since the organic poisons have been given a good deal of room. Within its compass the book gives a useful and reliable account of food poisoning and provides an adequate list of references to further sources of information. The author is on safer ground when dealing with the purely scientific aspects of the question; that his clinical observations are not always well founded is illustrated by his remark that the only two really important diseases from which the Salmonella infections need to be differentiated are dysentery and enteric fever. Readers introduced for the first time to the gruesome menace of botulism may be disappointed when they turn over the pages a second time to look for some comforting statement as to how this disease, fortunately extremely rare, can be prevented by the reheating of food. Many supporters of the cleaner milk movement in this country will feel that pasteurisation should have received more than one paragraph, and that arguments for and against its use cannot be fairly stated in a single sentence.

It has been said that food is the one subject in which everybody is interested. There is little doubt that this book will be widely read and act as a useful source of knowledge.

THE MENOPAUSE.

Die Wechseljahre der Frau. Von Privat-dozent Dr. HANS ZACHERL, Assistent der Universitäts-Frauenklinik in Graz. Vienna: Julius Springer. 1928. Pp. 127. R.M.750.

This paper-covered book on the menopause contains a series of post-graduate lectures delivered by the author. A section of ten pages deals with the physiology of the menopause, including its hygienic management, but the greater part of the book is concerned with its pathology, including hæmorrhage, diseases of the genitalia, and functional troubles such as vertigo, flushings, and other vascular and nervous phenomena. It is not to be expected that in such a slender volume all the diseases occurring at the menopause should be fully dealt with; for example, only about two pages are devoted to cancer of the uterus. The chief value of the work lies in the fact that attention is directed to diseases and functional disturbances *peculiar* to the menopause. In many respects the pathological nomenclature used differs from that familiar to British readers. Among the causes of menopausal metrorrhagia is included abnormal persistence of the Graafian follicle, which becomes cystic and palpably enlarged. The bleeding in these cases may be so severe as to lead to fatal anæmia, and is accompanied by enlargement and softening of the uterus and thickening of the mucosa. One of the commonest causes of pathological hæmorrhage at the menopause is stated to be defective power of inhibition of the corpus luteum leading to sudden ripening of the follicle. The ovary contains numbers of large and small, mostly atretic, follicles, and the endometrium undergoes hypertrophy and becomes polypoidal. Other causes of menopausal bleeding are fully discussed—e.g., arterio-sclerosis, vasomotor disturbances, and "adenomyosis." In the account of the last-named condition no note is taken of British or American work. The book is well worth the attention of British readers, if only for the frequency with which familiar conditions are viewed from an unfamiliar standpoint. A good discussion of the German literature on each subject is included, and a bibliography of some 300 references is appended.

EXPERIMENTAL MEDICINE.

An Introduction to the Study of Experimental Medicine. By CLAUDE BERNARD. Translated by HENRY COPLEY GREENE, A.M. New York: The Macmillan Company. 1927. Pp. 226. 12*s.* 6*d.*

THIS book, which first appeared in 1865, is now a classic. But the publication of Mr. Greene's excellent translation gives us an opportunity of directing the attention of the younger members of the profession, and especially of those engaged in research, to an admirable work. Every student of medicine knows of Claude Bernard as a great physiologist: few are aware that he sat in the Chair of Medicine at the Collège de France, while none, unless he has read this book, can follow closely the spirit in which his work was accomplished. This introduction to the study of experimental medicine, as Prof. Lawrence Henderson points out in his appreciation of the author, gives to the student some understanding of the art of research, and of the inevitable conditions and limitations of scientific discovery—in short, makes him understand what science really is. He will learn from the numerous examples which Bernard draws from his own investigations something of the working of the mind of a man of genius, notably the necessity for philosophic doubt, for the avoidance of fixed ideas, and for the preservation of freedom of mind. The book is more than a mere practical guide to the research worker as to how discoveries have been and are to be made. It meets and deals adequately with the criticism directed even to-day against experimental medicine by physicians of repute. The fact that medicine must always be something of an art does not imply that it should remain purely a science of observation. It is not sufficient merely to observe and foresee the course of diseases, and it is doubtful if even the most ardent disciple of Hippocrates acts up to the strict tenets of his faith by refusing to attempt in any way to alter their natural progress. Observation of patients must always be the constant basis of medical studies, empiricism acting more or less blindly is a valuable ally, but it is by the experimental method that we can most certainly isolate the essential elements of a disease, grasp its characteristics, and guide its treatment.

Paul Bert, the pupil and successor of Claude Bernard, praised this book for the masterly exposition of the rules of the experimental method, for the clarity of the attack on the great problems studied, and for its admirable literary style. In the translation these merits are no less obvious.

ALLEN'S COMMERCIAL ORGANIC CHEMISTRY.

Fifth edition. Vols. IV., V., and VI. Edited by S. S. SADLER, E. C. LATHROP, and C. A. MITCHELL. London: J. and A. Churchill. 30*s.* per vol.

VOL. IV. (740 pages) deals with the characteristic constituents and analysis of essential oils, resins, indiarubber, gutta-percha, balata, &c. The essential oils are discussed in two sections, one describing the individual oils, and the other the various chemical substances found in them. Comparison of this volume with the corresponding one of the previous edition shows that it has been largely rewritten and contains much new matter, more particularly in those sections dealing with general methods of analysis and with investigations of resins and of the important constituents of essential oils. The source and properties, physical and chemical, of these oils which play an important part in medicine, are set out clearly and concisely. The long interval between the publication of Vol. IV. and the two subsequent volumes caused some inconvenience to those who use this work for reference, and it is to be hoped that the concluding volumes will soon appear. The subject matter of Vol. V. (700 pages) includes tannins, the different kinds of ink, colouring matters of natural origin, and colouring substances in foods, benzene, aniline, pyridine, acridine bases, and so forth. Mr. Mitchell's discussion of inks is full of interest; there is a surprising amount of chemistry involved in their manufacture. Included in this volume are benzene and its homologues, logically leading up to the subject of colouring matters and synthetic dyes, to which the whole of Vol. VI. (658 pages) is devoted. This volume consists mainly of two long articles which cover the field of identification of the dyestuffs, and the testing of the substances obtained by splitting up the dye colour. To the colour chemist this volume will be invaluable.

THE price of "Simple Goitres," by Colonel R. McCarrison (Baillière, Tindall and Cox) is 10*s.* 6*d.*, and not as stated in our review of July 7th (p. 17).

THE LANCET.

LONDON: SATURDAY, JULY 21, 1928.

THE DEMAND FOR RADIUM.

THE International Conference on Cancer, the proceedings of which commenced on Tuesday morning last, has given already an opportunity for serious consideration in respect of the shortage of radium, which is occurring exactly at the period in its therapeutical history when its value is being definitely recognised. It can be taken for granted that, as the discussions in the various Sections of the Congress go forward, further evidence of this shortage will be forthcoming, but sufficient emerged on the first day of the proceedings to show that there is likely to be a demand for radium that cannot easily be satisfied, although it is the legitimate outcome of scientific investigation. It would seem to be a duty upon all authorities whom our profession immediately serve, to endeavour to obtain an improvement of the situation. Taking our own country as an example, there is no doubt that we are under-supplied with radium for medical purposes, and this can surely be said for other countries where medical research and scientific therapeutics are equally largely at the service of the community. The discussion at the International Conference on the relative value of surgery and radiation in the treatment of three of the most formidable regional divisions of malignant disease proves the difficulty of obtaining a sufficient supply of an invaluable weapon of treatment, and that this should be the situation to-day is tragic. For the use of radium in the treatment of cancer is not a new form of treatment or still in the speculative stage. It was introduced over 20 years ago, although at first the demand was small. Indeed, it may be said that for ten years after the introduction of the treatment the large majority of the medical profession was sceptical of the value of radium in malignant disease. Now, however, the position is altered, and those who are in touch with modern methods are convinced that radium, when properly applied, is a very valuable curative agent in malignant disease. This conviction has not been the outcome of any particular form of propaganda directed towards the optimistic view; rather it represents the massed opinion of a good many observers who have arrived at their conclusions individually, while to some extent the public also has been able to see the good results which have followed well-directed radium therapy, when the treatment has been applied properly to the appropriate cases. We may therefore assume that the medical advisers to the Ministry of Health are aware of the increased confidence now being placed in radium, and are also aware that in the not very distant future pressure may be put upon those in authority to assist in procuring it in response to urgent requiral.

It may be useful to pass in review some of the stages in the world's production of radium, and in particular to note the marked fluctuations in price. Soon after its discovery and isolation by Prof. CURIE and his wife, Madame CURIE, radium was prepared in several laboratories, when it was possible to sell it at as low a price as £2 per milligramme of the element. Then Prof. GIESEL in his laboratory at Brunswick, among others, prepared radium bromide of a high grade of purity at the same moderate price. When, however, radium began to be produced on a commercial scale the price rose rapidly, and throughout the war, when radium was in big demand for other than medical purposes, the price rose to £30 per milligramme of element. From that price it has fallen, but the figure is now about £12, and the price seems likely to remain about the same for intelligible reasons. The war had its special conditions, but it is natural to inquire whether there is any justification for charging £12 for an article which can on a laboratory scale be sold at a profit for £2. It would appear that here we have an unusual case where what is possible in the laboratory is not possible in the factory, and that small production is cheaper than large. The operations involved in the extraction of grammes from even a high grade ore is a large scale operation involving spacious premises, much labour, and many skilled operators, while at the moment there is but one source of mass supply of raw materials. At first Europe provided the supply, but, when the European reserves had been exploited, the American producers found that it paid them to extract radium from a very poor grade ore known as carnotite. This situation may have justified the enhanced cost, but now a find of much richer mineral in the Belgian Congo has resulted in the Belgian owners, the Union Minière de Katanga, becoming producers for the world of radium. Practically speaking, the radium that is now being bought and sold all comes from this source, while the monopoly bids fair to exist for some time. It would seem that only a discovery of a new source can ease the situation, but it would have to be a really rich deposit that was found before entry into competition with the existing producers would be profitable. All effort, however, to reduce the cost of radium is worth while. If medicine requires in this country say 20 g. of radium annually for the treatment of cancer about a quarter of a million pounds must be paid for it. This is a considerable sum even for a rich country to contemplate the spending of, while poor nations are hopelessly penalised at the present time.

The expense of radium makes it very necessary to consider, after it has been obtained, how it should be used, and what machinery, if any, can be put into action which will ensure its most efficient and most economical employment. If the proceedings at the Conference supply suggestive answers to these questions much practical good may result. Radium therapy has reached its present position largely as the result of a number of individual persons carrying out clinical work on cancer in an earnest spirit of investigation; a good many countries have contributed their individual researchers, and among these France is prominent indeed. It was right, therefore, that it should fall to Prof. CLAUD. REGAUD, the much respected head of the premier Radium Institute in the world, to open the first series of debates on the therapeutic value of radium, while his views on one of the questions set out above are already known. For Prof. REGAUD has expressed the opinion that it would be a mistake to increase in France the existing number of anti-cancer centres where radium therapy is employed, holding clearly that radium work is of a highly specialised kind and should be as far as possible centralised. This opinion may hold a very definite message for our country. Though there are no anti-cancer centres so-called in this country, there are quite a number of foci where radium therapy has been going on for some years. The radium investigations initiated by the Medical Research Council in 1921, and continued since then, need no special mention at this stage to our readers, but it might be well to bear in mind the 12 centres which are included in this scheme, and to realise that here, at any rate, are centres where current technique is known and practised, and where new modes are tried out and developed. It might therefore be profitable to discuss the possibility of such centres acting as coördination units in a national scheme of radium therapy. The extension of radium therapy to many of the poor-law institutions of the country would appear to be inevitable in some form or other, and they would have nothing to lose, but much to gain, by being affiliated with centres which have been through the difficult period of probation.

◆

THE PROBLEM OF HOOKWORM.

SEVEN years ago the conclusion was reached by certain workers on hookworm that it is futile to try to determine with the microscope whether the last ultimate parasite has been removed from an infected patient. Their technique was unspecified, but their dictum undoubtedly encouraged the practice of treating whole communities as infected on the ground that hookworm had been found in individuals. When this plan has been adopted the anthelmintic drug has sometimes killed people whose infection was quite unproved, and these casualties have brought into disrepute, and even ended, local campaigns against the disease. While CLAYTON LANE has clearly established how great are both the bionomic and economic human benefit accruing from disinfestation of a community paralysed by the disease, and has also shown that there is no scientific justification for the assumption that the lightly infected are of no importance in public health, he has condemned this herd treatment without diagnosis as impolitic, unscientific, and immoral. If this is so, there is no escape from the necessity to determine the presence or absence of the last ultimate hookworm. The proportions of the task may be seen in his estimate that 800 millions of mankind are infected with the worm. Since each person requires individual and accurate diagnosis, diagnostic technique becomes at once of prime importance.

Diagnosis must rest on examination of fæces for ova, and for this some method of concentrating ova and separating them from the obscuring fæcal material is necessary. With the vast numbers to be examined it is essential that both concentrative preliminary preparation and microscopical examination be made so far fool-proof that they can be delegated under supervision to the cheapest labour compatible with accuracy. The mass diagnosis of hookworm infection must be free from error and must not be costly. On the forbidding quest for a particular concentrative method which would best fulfil those conditions, CLAYTON LANE has spent ten years.[1] He adopted the principle, neglected by others, that any technique, "concentrative" or "control," which from the same evened quantity of fæces habitually delivered, quantity for quantity, more ova than did any other, was of necessity the most nearly accurate. Repeated testing, under similar conditions, of the various concentrative techniques in use, by such "control of controls," has given illuminating results. In this searching trial the method of direct centrifugal floatation (D.C.F.) which he devised, developed, and standardised, has proved the most efficient for those who require certainty in diagnosis of the presence or absence of hookworm ova, and accuracy in counting them. Its accuracy and easy readiness in use have already been demonstrated both in the hospital laboratory in England and in the hookworm field in the tropics, where its more extended employment, as it is inexpensive, waits only on wider publicity for its advantages. D.C.F., in the first or diagnostic spin, and using rapid lift, collects on the average 80 per cent. of the hookworm ova present in 1 c.cm. of fæces in a light infection. Pushed to finality it has not shown an ovum content persistently less than about 30 ova per c.cm., but CLAYTON LANE has marshalled cogent evidence to show that this represents "the minimum ovum content normal for hookworms"—that is, the number of ova present in 1 c.cm. of fæces if a single female is ovipositing normally.

Direct centrifugal floatation collects trichostrongylus ova with the same facility as it does hookworm ova, and also, in striking manner, giardia cysts. Its author is to be congratulated on a patient and admirable research whose result, long needed, is of immediate usefulness and value. It makes possible that high diagnostic efficiency which, he insists, is indispensable if the hookworm problem is to be solved by humane and scientific means; for however convinced an administration may be of the moral and material benefits of disinfestation, the money is nowhere available in the tropics to carry this out on a country-wide scale. Every farthing, therefore, spent on every section of the campaign must be made to produce the greatest possible benefit; and it has not yet been seriously envisaged that prevention of infection for most of the hundreds of millions of human beings now exposed to infection and reinfection can proceed otherwise than by expulsion of the parasite from those carrying it. It is true that if all wore boots, or could use the conveniences of a water-borne sewage system, the infection would become a rarity. In fact the 800 million infected are barefooted, and—what is vital to the problem—are left to their own particular, and too often peculiar, fancy as to where they shall defæcate. Attempts to control this wayward fancy are wisely held up until effective latrine systems can be devised. The only basis of efficiency here is accurate knowledge of the bionomics, and especially the migratory powers of the infective ankylostome larva. Its life in fæcal material and soil has repeatedly been studied, notably of late by many American workers. Vertical migration of the larvæ was noted, but their recovery from a culture has been considered a dependable measure of the number that had developed; and their disappearance a token of their death. Then FÜLLEBORN'S experiments demonstrated that strongyloides larvæ at the infective wandering stage migrated in every direction and every plane. Now CLAYTON LANE[2] shows by ingenious experiments, in conditions in which there was control of single factors, that ankylostome larvæ migrate laterally as well as up and down; and that, in hydraulic or other conditions favourable for migration, the better nourished and the more vigorous (that is, more capable of producing infection) the larvæ, the fewer will remain behind to be enumerated. Their absence often signifies not their death but their vicious vitality. In his experiments every culture was surrounded by a water trap into which the migratory infective larvæ tumbled. It was noted that few escaped from this water trap—a plain pointer to the style and form of the effective anti-ankylostome latrine. Untrapped cultures, therefore, can afford no assured indication as to viability of hookworm ova, longevity of larvæ in soil, or their migratory capabilities. And it is on untrapped cultures that nearly the whole of our supposed knowledge on these essential matters is at present based.

DICHOTOMY OR FEE-SPLITTING.

WE published last week a letter from a correspondent, who gave a very good reason for remaining anonymous, on what he described as an obnoxious practice which he had reason to believe is rapidly extending in certain parts of London. This practice consists in the diversion of part of a consultant's fee, without the knowledge of the patient, to the practitioner who has advised the consultation. The patient believes that his whole payment is made to the surgeon or physician who has been called in, whereas part of the fee has, in fact, been deducted as a commission for the practitioner. There are, we have been assured, a large number of consultants in this country who have no cognisance of any such practice, and these may be inclined even to question its occurrence, but it may be recalled that several years ago, in accordance with a widely felt desire, a meeting of consultants and specialists was called in a provincial centre to discuss the practice, and two resolutions were passed and circulated to all the practitioners in the neighbourhood. The resolutions were worded thus :—

1. It is improper for a Consultant to transfer any portion of his consultation- or operation-fee to the Practitioner who has called him in. The Consultant who offers or agrees to such payment, however innocently, is open to the suspicion of paying a "commission" for his own advantage. The Practitioner who accepts or asks for it cannot maintain the position of a trusted and unbiased adviser as to the need for a consultation and the selection of a Consultant.

2. No Consultant or Specialist shall pay to the General Practitioner who is associated with him in a case any part of an operation-, consultation-, or so-called "inclusive" fee, unless he informs the patient or his representatives of the services for which the payment is made and the amount of such payment.

The situation is one which has been freely discussed for some time past in the United States of America, and at its April meeting the New York Medical Society received a report on the subject from its Committee of Economics. This report was, it appears, tabled without any vote being taken upon it, and our contemporary, *American Medicine*, in expressing its disapproval of the abortive result adds it would be interesting to have some patient sue a member of the profession for the return of money known to have been paid to the doctor referring the case. The word "known" is the crux, for in this country and, presumably, also in the United States, both the offer and the acceptance of a secret commission are punishable at law, and evidence is therefore difficult to come by. A mass of information is, however, now available owing to the action of the *Medical Journal and Record* (of New York) in throwing open its columns to its readers in the form of an "open forum," without editorially taking any sides in the matter. A questionaire was submitted to readers with the remark: "We want you to have your say, and we want you to be indulgent enough, if indulgent it may be called, to hear what the other man has to say, and so the matter stands. This is your department. Make use of it." The material result has been some 55 columns of print embodying the personal views of several hundreds of doctors. These views are extremely varied. Two groups, as no doubt was to be expected, predominate—namely, those who wish to deny, with more or less emphasis, the existence of the practice at all; and those who have utilised the opportunity for criticising the behaviour of their colleagues with an extreme, if not imaginative, freedom. It seems clear, from the mere number of the former group, that there are many members of the medical profession, especially in the Eastern States and their large towns, who have not come in contact with fee-splitting at all; whereas it is equally evident that in the Middle West, and still more in the Southern States and in Texas, fee-splitting is by no means exceptional. A New Orleans correspondent states that in Louisiana it is a common practice; in Alabama it seems to have been almost a rule 15 or 20 years ago, although not nearly so prevalent now; in Ohio a signed contribution states that it is universal, while a Wilmington practitioner understands, in a general way, that many of the general surgeons and specialists in Cincinnati split fees with small-town doctors who refer them cases. A Minnesota physician remarks that the practice is quite inevitable under present conditions, the large fees received by surgical specialists being its foundation. The ex-president of Iowa State Medical Society says, quite frankly, that 75 per cent. of the doctors of Iowa and Nebraska "want splits." These examples may suffice to give some idea of the relative prevalence of fee-splitting in the various United States. The report does not cover Latin America, if only for the reason that division of the total fee paid between the specialist and the family doctor is apparently the accepted practice there.

Something has already been said, incidentally, regarding the circumstances which have brought about such a state of affairs. A New York correspondent's statement may be given as an example. He writes: "The newcomer, or unknown specialist, in his desire to increase his clientèle, *offers* part of his fee as an inducement to the family physician. Many young surgeons find it impossible to build up a practice any other way. Some prominent specialists with good followings take into consideration the plight of the referring physician and give him a portion of the fee on the basis of good fellowship." For these reasons he regards the hope of eliminating fee-splitting completely from medical practice as rather meagre, and there is, in fact, throughout the symposium not only a wide admission of the practice and of its inevitability, but a good deal of justification for it. The legal profession, writes a Baltimore physician, splits fees and finds nothing wrong with it. (The analogy would fail in this country if applied to a busy barrister sharing his fee with another barrister who has devilled a case for him, for there is no element of agency.) A New York physician feels that for the younger man fee-splitting should be legitimatised, for it cannot be eradicated. As a remedial measure another suggests the sharing openly of the surgical fee between the surgeon and the practitioner who refers the case, the surgeon receiving two-thirds or three-quarters of the fee, and the medical man openly receiving one-third or one-quarter. An official of the Prudential Insurance Company remarks that fee-splitting amounts to doing the right thing in the wrong way. From Denver comes the suggestion that the patient should be informed of the fact that the diagnosis of the surgical condition by the attending physician is frequently worth as much to the patient as the operation itself. The practitioner should therefore have courage enough to charge for his diagnosis and time; and, if need be, the specialist should mention to the patient that he is cutting down his fee so that the patient can pay the family doctor. The hardship is specially well stated by a New York contributor, who writes: "The family physician who calls with his patient to the consultant and spends from two to three hours or more, or visits the operating room, he is entitled to a reasonable fee. The patient should be told by the consultant or surgeon that his fee covers the fee for services of the family physician. *Call* it a collective fee or what you please. Patients will not pay the family physician any additional conference fee." And another remarks: "It is rather peculiar that it is perfectly ethical for the surgeon to pay his assistants out of his fee and yet not allow the family physician to assist and pay him." The situation is summed up in an article by Dr. A. L. Wolbarst, of New York, who after acknowledging that fee-splitting is a serious evil and one growing by leaps and bounds (not only in America but in Europe as well), describes it as the natural out-growth of the widespread specialisation in medicine, which Dr. Thayer deplored in his presidential address to the American Medical Association last month. Both the surgeon and the practitioner have come to realise that prosperity realise that here, at any rate, are centres where current technique is known and practised, and where new modes are tried out and developed. It might therefore be profitable to discuss the possibility of such centres acting as coördination units in a national scheme of radium therapy. The extension of radium therapy to many of the poor-law institutions of the country would appear to be inevitable in some form or other, and they would have nothing to lose, but much to gain, by being affiliated with centres which have been through the difficult period of probation.

THE PROBLEM OF HOOKWORM.

SEVEN years ago the conclusion was reached by certain workers on hookworm that it is futile to try to determine with the microscope whether the last ultimate parasite has been removed from an infected patient. Their technique was unspecified, but their dictum undoubtedly encouraged the practice of treating whole communities as infected on the ground that hookworm had been found in individuals. When this plan has been adopted the anthelmintic drug has sometimes killed people whose infection was quite unproved, and these casualties have brought into disrepute, and even ended, local campaigns against the disease. While CLAYTON LANE has clearly established how great are both the bionomic and economic human benefit accruing from disinfestation of a community paralysed by the disease, and has also shown that there is no scientific justification for the assumption that the lightly infected are of no importance in public health, he has condemned this herd treatment without diagnosis as impolitic, unscientific, and immoral. If this is so, there is no escape from the necessity to determine the presence or absence of the last ultimate hookworm. The proportions of the task may be seen in his estimate that 800 millions of mankind are infected with the worm. Since each person requires individual and accurate diagnosis, diagnostic technique becomes at once of prime importance.

Diagnosis must rest on examination of fæces for ova, and for this some method of concentrating ova and separating them from the obscuring fæcal material is necessary. With the vast numbers to be examined it is essential that both concentrative preliminary preparation and microscopical examination be made so far fool-proof that they can be delegated under supervision to the cheapest labour compatible with accuracy. The mass diagnosis of hookworm infection must be free from error and must not be costly. On the forbidding quest for a particular concentrative method which would best fulfil those conditions, CLAYTON LANE has spent ten years.[1] He adopted the principle, neglected by others, that any technique, "concentrative" or "control," which from the same evened quantity of fæces habitually delivered, quantity for quantity, more ova than did any other, was of necessity the most nearly accurate. Repeated testing, under similar conditions, of the various concentrative techniques in use, by such "control of controls," has given illuminating results. In this searching trial the method of direct centrifugal floatation (D.C.F.) which he devised, developed, and standardised, has proved the most efficient for those who require certainty in diagnosis of the presence or absence of hookworm ova, and accuracy in counting them. Its accuracy and easy readiness in use have already been demonstrated both in the hospital laboratory in England and in the hookworm field in the tropics, where its more extended employment, as it is inexpensive, waits only on wider publicity for its advantages. D.C.F., in the first or diagnostic spin, and using rapid lift, collects on the average 80 per cent. of the hookworm ova present in 1 c.cm. of fæces in a light infection. Pushed to finality it has not shown an ovum content persistently less than about 30 ova per c.cm., but CLAYTON LANE has marshalled cogent evidence to show that this represents "the minimum ovum content normal for hookworms"—that is, the number of ova present in 1 c.cm. of fæces if a single female is ovipositing normally.

Direct centrifugal floatation collects trichostrongylus ova with the same facility as it does hookworm ova, and also, in striking manner, giardia cysts. Its author is to be congratulated on a patient and admirable research whose result, long needed, is of immediate usefulness and value. It makes possible that high diagnostic efficiency which, he insists, is indispensable if the hookworm problem is to be solved by humane and scientific means; for however convinced an administration may be of the moral and material benefits of disinfestation, the money is nowhere available in the tropics to carry this out on a country-wide scale. Every farthing, therefore, spent on every section of the campaign must be made to produce the greatest possible benefit; and it has not yet been seriously envisaged that prevention of infection for most of the hundreds of millions of human beings now exposed to infection and reinfection can proceed otherwise than by expulsion of the parasite from those carrying it. OCULAR MUSCLE BALANCE IN FLYING MEN.

THE successful handling of aircraft makes a big demand on visual acuity and balance. In examining pilots for flying aptitude, consideration was given mainly to visual acuity until it became established that "fast landers" almost uniformly possessed good visual judgment, whereas a large percentage of those who could not land manifested defective visual judgment. This led to tests for visual judgment being added to the usual routine ophthalmic examination. The tests deemed sufficient to expose the presence of muscle imbalance in flying personnel are set out on pp. 141 ff. of the Manual for Medical Officers of the Royal Air Force.[1] They include: (*a*) the convergence test; (*b*) the cover test; (*c*) the red-green (phorometer) test; (*d*) the Bishop-Harman diagram test. A typical case of poor response to the four tests mentioned would be one in which: (*a*) the convergence near point is over 4 in.; (*b*) the cover test reveals "neglect" or suppression in the case of the covered eye, so that it either failed to take up fixation or reacted in a very sluggish manner after being uncovered; (*c*) there is a separation of four or more inches (1–2 prism dioptres) between the superimposed red and green lights at 20 ft. or a marked hyperphoria; (*d*) a diaphragm result of four or worse (normal 0–1). Subjects with muscle imbalance, practically without exception, take a time considerably over normal before they learn to land—some, indeed, never learn to land at all. Those who show a tendency to exophoria flatten their machines out too early; those with esophoria are inclined to flatten out too late, and fly into the ground. These defects are naturally the more accentuated the faster the landing speed of the machine. That defective visual judgment, as demonstrated by the tests described, is actually the cause of many landing troubles has been amply proved by the effects of visual training, both on those pupils who had failed to qualify, or who were indifferent pilots when qualified, and on those pilots who concomitantly with disease or accident had developed ocular muscular defects. Visual training carried out either by means of Worth's amblyoscope alone, or combined with the stereoscope, as demanded by the type of case, has proved of great value. It is stated that pilots who were a trial to their instructors, and a source of danger to themselves, have, after successful training, not only developed into sound flyers, but have, in a number of instances, become well known as instructors at flying schools. Exceptions naturally arise from time to time as, for example, when a man has superimposed handicaps such as lack of flying temperament or inability to perform the fine coördinated movements inseparable from modern light machine flying. It appears that the most simple cases are those of pure exophoria which are found in pilots who: (*a*) had a tendency towards this condition on entry not sufficient to warrant rejection; (*b*) suffered from some illness, such as influenza, malaria, sandfly fever, or became gradually debilitated from tropical service; or (*c*) suffered from cerebral concussion after some accident. Types (*a*) and (*b*) require training for their correction; type (*c*) shows, in some instances, a remarkable power of righting with time unless the continued irritation of a diplopia has produced the monocular habit as a way of escape. Less simple are the esophorias, whether of the usual form with hypermetropia as a basis, or the so-called pseudo-esophoria of spasmodic character, produced sometimes by sun-glare, sometimes as a subconscious means of mastering the inroad of a mild exophoria. This condition raises the problem of the irregular control of nerve impulses, and it is open to controversy how it is acquired. An interesting type is that in which the "neglect" or "suppression" factor is predominant either as "monocular neglect" or "alternating neglect." In the first instance, one eye receives and registers continual impressions while the other registers impressions irregularly; in the second, one eye functions for a time and then gives way entirely to the other, and so on. The pilot with "alternating neglect" tends to fly his machine after the zigzag fashion of the snipe. In training these cases the "neglect" factor must first be dealt with if satisfactory results are to be obtained. Finally, there are a few pilots of the war school who possess only one useful eye. They have either lost the use of one eye in infancy and have acquired the "monocular sense," or have been spared the "master eye," and then fly, as it were, along a "memory sagittal line." There is much else of interest in the Manual; we have selected for comment a subject of immediate topical interest.

BOARD OR DEPARTMENT?

THE Reorganisation of Offices (Scotland) Bill, which is likely to become law before Parliament rises for the vacation, proposes to substitute Departments for Boards in the administration of health, agriculture, and prisons north of the Tweed. The Bill has other miscellaneous provisions relating to certain ancient legal offices, but the proposed changes in the constitution of the Scottish Board of Health and the Board of Agriculture for Scotland are those which have attracted the main attention. As in the similar Bill of 1924, they involve deleting the requirement that two medical practitioners, one or more women, and one practising lawyer shall be statutory members of the body administering health services in Scotland. These alterations will chiefly be viewed from three aspects. There is first the personal view, important enough to those whom it immediately concerns but liable to be overlooked by others—the view of particular officials whose prospects of promotion or superannuation may be affected. Next there is the wider view, suffused with the warm atmosphere of local patriotism—the view of those Scots who are satisfied with the institutions they have got and who are distrustful of any movement which may threaten the freedom of national contacts or may place some college-bred theoretically minded officialism above the native common sense and practical ability of Scotland. Finally, and at a marked disadvantage in popular support, there is the cold official aspect of a superior efficiency in administration, an impersonal abstraction associated perhaps in the all-seeing eye of the Treasury with some future prospect of economy or of a more perfectly standardised civil service free from any element of local patronage. The government of Scotland has its peculiarities and anomalies. By reason of the undeniable supremacy of the Parliament at Westminster there must be some minister in London—sometimes named the Secretary for Scotland, at other times (as now) one of His Majesty's principal Secretaries of State, specially charged with Scottish affairs—to answer for the conduct of Scottish government. Simultaneously the actual work of administration must be conducted at Edinburgh or elsewhere in Scotland by officers who have first hand acquaintance with the problems of that work. Thus there has been evolved at Dover House (the Scottish Office in Whitehall) a sort of post office or clearing house, an institution which would break down at any moment if it were not operated with remarkable competence and almost exclusively by a Scottish personnel. The Secretary of State has to consult the branches of Scottish administration in the north. He naturally knows it to be easier to communicate with a single official, the carefully selected head of a department, than to take the opinions and recommendations of the several members of a board which may not be unanimous. The board's advice may be a compromise, or the minister may have to adjudicate between the dissenting voices of majority and minority, and he knows that a collective mind is made up more slowly than that of a single individual.

There, then, is the issue. Is the Secretary of State to consult one person or many? Is he to deal with a super-civil servant or with a group of possibly independent advisers? If he listens to the expert administrator, will there not be a tendency to override or lies in the close economic coöperation which is represented by the split-fee. Under existing practice, the amount of the specialist's fee is paid to him, and he either retains it entirely, or returns part of it secretly to the family doctor, in the form of the illicit split-fee. "The time has come," he says, "for a revision of the code and for recognising the principle of open ethical fee-sharing as just and equitable." This modification of the code should provide that the specialist's fee shall include the doctor's fee, and it shall be deemed as much a violation of the code for the specialist to withhold the doctor's rightful share as for the doctor to demand, or the specialist to offer, more than the duly established proportion. He does not regard the plan as perfect, but submits it as likely to improve the position of all three parties to the bargain.

The symposium may, as we have suggested, not represent very closely the average medical view in the United States, but it will have afforded an opportunity of utterance for extremists in both directions. Nevertheless no one can read the testimony brought forward in this "open forum" without gaining the impression that there is a situation which is not being met by ethical action alone, and may require some adjustment to the changing conditions of medical practice, especially in relation to the development of specialisation in America.

Annotations.

"Ne quid nimis."

PNEUMONIA ON THE RAND.

In 1912, following a visit to the Rand by Sir Almroth Wright, a system was inaugurated of routine prophylactic inoculation of natives employed in the mines against pneumococcal infections. Since the independent discovery by Sir Spencer Lister, working at the South African Institute for Medical Research, and by American observers, that pneumococci can be separated into different serological groups, the vaccine used has been a mixed one. In 1919 [1] we commented on the progressive fall in the incidence and mortality-rates of lobar pneumonia in the large population at risk. The average annual death-rate for the years 1908 to 1911 was about 12 per 1000. After that it fell steadily, with the exception of a rise in 1915, which coincided with a reduced issue of vaccine; by 1918 it was already less than 4 per 1000. The descent in the curve has been attributed in South Africa and elsewhere to the use of the vaccine.

Unfortunately, though prophylactic inoculation is still being zealously carried out and the efforts to improve the hygiene of life in compounds have certainly not been relaxed, during the last few years the incidence- and mortality-rates have shown a tendency to rise. In the important group of mines controlled by the Rand Mines, Ltd., for example, the mortality-rate, which was under 1·5 per 1000 in 1920, has since risen again irregularly, until in 1927 it was only just under 5. An attempt to ascertain the factors responsible for this disappointing rise has recently been made by the Transvaal Mine Medical Officers Association. In August, 1927, following on a communication from the Gold Producers' Committee, the Association appointed a subcommittee, consisting of Dr. A. J. Orenstein (convener), Dr. H. Butt, Dr. A. Frew, and Dr. C. Scholtz, to report on the serious increase in mortality from disease among natives in the earlier months of 1927. For this increase the pneumonias were found to be mainly responsible. The subcommittee issued a questionaire to all mine medical officers in September last, and a critical summary of the information received is the substance of their report, which has now been printed in the Proceedings of the Transvaal Mine Medical Officers Association (April, 1928). The data under review concern the natives employed in 30 mines during the periods from Jan. 1st to August 31st in 1926 (168,000 boys), and in 1927 (166,000 boys). Of these, approximately 94,500 in each year were South African natives, the rest being from the East Coast. Both lobar and broncho- and influenzal pneumonias were studied and the tables and statistics on which the conclusions are based are set out in full. Some interesting results have emerged. For example, in both years approximately half the cases of lobar and of bronchopneumonia occurred in the first three months of employment; no definite correlation was observed between recruiting ratios and incidence and mortality from any form of pneumonia. The case mortality varied only slightly, showing that the severity of the attacks was not markedly different in the two years. The chief conclusions reached are that the physique of the native recruits plays a considerable rôle in both attack-rate and mortality-rate from the pneumonias; that natives sleeping singly in partitioned-off concrete bunks are less prone to attacks of pneumonia; that there is probably a periodicity in the incidence of pneumonias, and that the Witwatersrand mines are now going through a period of rise in the curve of incidence. A graph giving the incidence of pneumonias in Chicago between the years 1867 and 1925 lends support to this suggestion. No ground was found for any suspicion that slackness in vaccination might be responsible for the increased incidence and mortality. Some of the statistics on lobar pneumonia among underground workers seemed to indicate that pneumococcal vaccine gives better prophylactic results in one 2 c.cm. dose than in three c.cm. given in divided doses, which is the more usual method. On one mine only one inoculation of 1 c.cm. of pneumococcal vaccine was used, and except in the incidence of lobar pneumonia among East Coast natives, this mine had a smaller incidence than the average for all the mines. The recommendations made are that the physical standard of recruits should be correlated with that recommended by the Association, that all compound rooms should, as soon as possible, be fitted with partitioned-off concrete bunks, and that the whole matter of prophylactic vaccination should be exhaustively examined at an early date. At the meeting of the Transvaal Mine Medical Officers Association, to which this report was presented,[2] some of the medical officers spoke in favour of discontinuing inoculation. A better plan, and one which is likely to be adopted, is the suggestion that the natives on each mine should be divided into equal batches, of which one only should be inoculated. If administrative difficulties prevent this simple differentiation of employees, a certain number of mining areas could be set apart and used as controls. The opportunity for a clear test seems to have arrived. While the incidence- and mortality-rates were decreasing, it might not have been justifiable to withhold prophylactic treatment. But when these rates are rising, in spite of vaccination, there can be no ethical reason why a large-scale experiment should not be tried. It would be difficult to believe that the dramatic fall of the curve of lobar pneumonia in the years following 1912 was an epidemiological phenomenon independent of prophylactic vaccination; but should a controlled test on a rising curve show that vaccines have but little effect, the whole question will have to be reopened, since the expense involved must be considerable. The stumbling-block against the acceptance of the efficacy of vaccination has always been the fact that an attack of pneumonia confers no immunity, but the apparent success of inoculation in South Africa has been an argument difficult to controvert. The Transvaal mine medical officers have now an opportunity to devise a series of crucial tests which should provide definite evidence for or against the value of prophylactic inoculation against pneumonia.

OCULAR MUSCLE BALANCE IN FLYING MEN.

THE successful handling of aircraft makes a big demand on visual acuity and balance. In examining pilots for flying aptitude, consideration was given mainly to visual acuity until it became established that "fast landers" almost uniformly possessed good visual judgment, whereas a large percentage of those who could not land manifested defective visual judgment. This led to tests for visual judgment being added to the usual routine ophthalmic examination. The tests deemed sufficient to expose the presence of muscle imbalance in flying personnel are set out on pp. 141 ff. of the Manual for Medical Officers of the Royal Air Force.[1] They include: (*a*) the convergence test; (*b*) the cover test; (*c*) the red-green (phorometer) test; (*d*) the Bishop-Harman diagram test. A typical case of poor response to the four tests mentioned would be one in which: (*a*) the convergence near point is over 4 in.; (*b*) the cover test reveals "neglect" or suppression in the case of the covered eye, so that it either failed to take up fixation or reacted in a very sluggish manner after being uncovered; (*c*) there is a separation of four or more inches (1–2 prism dioptres) between the superimposed red and green lights at 20 ft. or a marked hyperphoria; (*d*) a diaphragm result of four or worse (normal 0–1). Subjects with muscle imbalance, practically without exception, take a time considerably over normal before they learn to land—some, indeed, never learn to land at all. Those who show a tendency to exophoria flatten their machines out too early; those with esophoria are inclined to flatten out too late, and fly into the ground. These defects are naturally the more accentuated the faster the landing speed of the machine. That defective visual judgment, as demonstrated by the tests described, is actually the cause of many landing troubles has been amply proved by the effects of visual training, both on those pupils who had failed to qualify, or who were indifferent pilots when qualified, and on those pilots who concomitantly [illegible] disease or accident had developed ocular muscular defects. Visual training carried out either by means of Worth's amblyoscope alone, or combined with the stereoscope, as demanded by the type of case, has proved of great value. It is stated that pilots who were a trial to their instructors, and a source of danger to themselves, have, after successful training, not only developed into sound flyers, but have, in a number of instances, become well known as instructors at flying schools. Exceptions naturally arise from time to time as, for example, when a man has superimposed handicaps such as lack of flying temperament, or inability to perform the fine coordinated movements inseparable from modern light machine flying. It appears that the most simple cases are those of pure exophoria which are found in pilots who [illegible] had a tendency towards this condition [illegible] not sufficient to warrant rejection; (*b*) [illegible] illness, such as influenza, malaria, [illegible] or became gradually debilitated from [illegible] service; or (*c*) suffered from cerebral concussion [illegible] some accident. exclude the technical expert in health, housing, or agriculture? The Scottish Members of Parliament who object to the Bill have pointed out that there is no allegation of existing inefficiency; they have specially praised the administration of the boards which deal with health, agriculture, and prisons; they maintain that the proposals mean the denationalisation of Scotland and will hasten the advent of home rule. On this wider issue of autonomy and national sentiment Scotland will find support from the Welsh Members of Parliament who have lately been protesting against the proposed reorganisation of the Welsh Board of Health. To the latter the Minister of Health has replied that the abolition of a chairman and the reduction of the Welsh Board from four to three members is not part of a policy of denationalisation; the Board has not been an executive body; it has met not more than 28 times in the past nine years; its work is done by individual members in their individual capacities; the present change is a matter of internal administration only, a question of personal arrangements. This question of personal arrangements arises also in the Scottish proposals. The existence or the near prospect of certain vacancies has caused the administrative changes to be pressed forward now at a moment when they can most smoothly be effected. Sir John Gilmour appears to have given some kind of assurance that he will hold himself as accessible to his technical advisers as heretofore, though he frankly maintains that experts must be controlled. We do not, he observed, allow the military and naval experts to carry out all they desire. Similarly, "if the medical man had his way, he might possibly impose upon Parliament and the country a system eminently desirable no doubt but so extravagant or so much in advance of the time that Parliament could not tolerate it." Sir John Gilmour's best argument is that every inquiry and commission which has examined the science of administration has recommended the change he proposes. England has a Board of Admiralty and a Board of Inland Revenue; she has a Board of Trade (of which the Archbishop of Canterbury is a member amongst others), but fortunately this Board can act with a quorum of one member. Apart from these instances, this country has usually adopted the system of ministries and departments, administered under a single permanent head, and in recent years Northern Ireland has found it worth while to copy the same model. Board or Department—it is not the label that matters but the sympathetic intelligence which the Scottish Office will no doubt continue to supply.

INDICAN IN THE BLOOD.

In 1924 C. H. Andrewes described in our columns[1] a new colour reaction which occurred on adding van den Bergh's diazo-reagent to the serum of patients with uræmia. His observations have been confirmed by other workers, and the test has been found of use in helping to diagnose the condition of renal failure. Andrewes failed to discover the nature of the substance which gave this reaction, but recently G. A. Harrison and R. J. Bromfield have shown[2] that the colour is given by an indoxyl compound presumed to be indican, which is potassium-indoxyl-sulphate. Indoxyl is formed in the body from tryptophane, one of the principal amino-acids in the protein molecule. The amount of indoxyl which is formed depends partly on the quantity and nature of the protein which is eaten, partly on the nature of the bacterial flora of the intestines. The indoxyl which is absorbed from the intestines combines (in the liver) with sulphuric acid, and the resulting indican is then passed on into the blood. If the kidneys are functioning properly, the amount of indican circulating in the blood is very small as it is excreted in the urine. The amount in the blood depends on four factors—namely, the quantity of tryptophane in the diet, the nature of the bacterial flora, the efficiency of the liver, and the efficiency of the kidneys. It has been found that the diazo-colour reaction runs roughly parallel with the concentration of urea and creatinine in the blood of uræmic patients, although the test occasionally proves negative. F. S. Patch and I. M. Rabinowitch[3] claim that in urological cases the diazo-test enables them to judge whether the excess of urea is of serious importance or not. This claim may have to be reconsidered now that the cause of the colour reaction is known to be indican, since in spite of gross renal damage, indican may not be present in excess in the blood owing to the failure of one of the factors necessary for its formation. Harrison and Bromfield are to be congratulated on their success in elucidating the cause of a colour reaction given by so complex a fluid as blood.

A FORGOTTEN RED CROSS PIONEER.

The recent centenary celebration of the birth of Henri Dunant has stimulated the memory of Ferdinando Palasciano, surgeon to the army of the Neapolitan Bourbons, and his courageous advocacy of mercy to the wounded on the field of battle. From an account of his career by Prof. Cesare Baduel, director of the Italian Red Cross, we learn that Palasciano was early conscious of his responsibilities to soldiers, not only when they were effective combatants, but also when they were suffering and abandoned on the field of battle. At the present time it reads strange that, during the Sicilian insurrection against Bourbon rule in 1848, General Filangieri, who was besieging Messina, gave orders that no quarter was to be given to the enemy. Palasciano disregarded these orders and cared for the wounded of both sides. For this act of insubordination he was threatened with death, and he had to spend a year in prison as a reward for his clemency. Filangieri's persecution of Palasciano would doubtless have been more brutal had not King Ferdinand known him personally and valued him both as a man and as a scientist. In January, 1861, he offered to the Accademia Pontaniana at Naples a prize of 100 ducats for the best 100 rules of military surgery for the treatment of gunshot wounds. The prize was not awarded at first, but it was won some time later by Dr. Appia, of Geneva, and the Italian, De Vita. In connexion with this competition Palasciano declared before the Accademia Pontaniana that "belligerent powers, in their declaration of war, must recognise reciprocally the principle of the neutrality of the wounded and seriously ill; for the entire period of their treatment." He insisted that the principle of the neutrality of the wounded should be accepted, either by the ruling of an international congress, or by a special agreement between the belligerent powers inserted in the declaration of war. Five of his points were: (1) That the armies should be obliged to exchange wounded prisoners immediately after a battle. (2) All soldiers who were too severely wounded to be transported should be treated on the field of battle by the army's own sanitary service. (3) A sanitary staff, sufficient to care for wounded men in hostile territory, should be given a safe conduct and escort, and be allowed to remain until their task was finished, when, during a truce, the personnel could return to their own advanced post or to the frontier of the enemy's country. (4) All necessary food, lodging, and drugs should be provided by the Commissariat on the signature of the attending surgeons and on the assumption that reimbursement should be effected after the war. (5) In the case of sieges, and in addition to the exchange of the wounded, the besieged army should be allowed to send its wounded to any neutral country willing to receive them if the besieging army would not do so. In 1862 Henri Dunant published his "Souvenir de Solferino," which did so much to pave the way for the international conference of 1863. The International Convention, signed in August of the following year, neglected the fate of wounded men in naval battles. Palasciano insisted on the importance of this omission and appealed to the Italian Government to call another conference. The governments interested having come to an agreement, the Swiss Federal Council held another conference at Geneva in 1868. Palasciano did not attend it, but the amendments which he advocated to the Convention were adopted. He died on Nov. 28th, 1891, and was buried in the ground reserved for eminent men in the cemetery of Poggioreale at Naples.

ULTRA-VIOLET LIGHT APPLIED TO DISEASES OF THE EYE.

FROM the Ultra-violet Light Clinic, established at the Royal London Ophthalmic Hospital in the autumn of 1925, some interesting results are reported by Dr. W. S. Duke-Elder.[1] The 425 cases treated up to July, 1927, are classed into those in which general sun-baths were given and those in which the rays were applied directly to the eye. The number treated by general light baths was 306. Of these, roughly, one-third were cases of iritis and irido-cyclitis, one-third of phlyctenular keratitis, and the remainder of other diseases. The chief interest of the report lies in the cases of chronic and intractable iritis and irido-cyclitis, which have been treated without success for periods of months or years by all the known methods of therapy and which have responded well to the ray treatment. Of 76 cases of infective irido-cyclitis treated, 38, or just half, were cured, 30 showed more or less improvement, and only eight showed none. An eye, which has been the seat of active inflammation for many months, may well become quiet. On the other hand, gross structural changes are as unalterable under this as under any other treatment. Of 16 cases of choroiditis treated, the infective and the tuberculous cases did well, especially cases with persistently recurring lesions. Syphilitic cases did not respond to the treatment. Cases of scleritis and sclero-keratitis did well, and cases of phlyctenular keratitis, including extremely chronic relapsing cases, did best of all. Light may be considered almost a specific for this disease. The same may be said of obstinate blepharo-conjunctivitis occurring in debilitated patients. Duke-Elder's conclusion is that with judicious use the effects of ultra-violet light can be powerful for good, but they have their limitations and they always stop short of the marvellous. The main danger to be guarded against is over-dosage, and some patients may display an idiosyncrasy and develop symptoms of over-dosage, even while the exposures are kept well within the limits ordinarily safe. Care in this respect is especially to be insisted on in the case of patients with low blood pressure. Pyrexia is usually a contra-indication and care must be taken during menstrual periods. With regard to special effects on the skin and the eye, there is the danger of burns from excessive doses and of cataract, which must always be guarded against by the wearing of protective glasses. Direct radiation of the eye was used in 119 cases. This method involves real danger of producing cataract unless the most elaborate precautions are taken, and Duke-Elder has only employed it by means of a special ophthalmic radiation lamp, by which the desired rays are filtered off from the rest and focused accurately on the desired depth. Hence the method is only applicable for the cornea, sclera and conjunctiva, and theoretically, perhaps, with a very obliquely directed radiation, the anterior surface of the iris. Actually, of 119 cases so treated, 99 were infections of the cornea and sclerotic, 20 of varying types of conjunctivitis. All types of corneal ulcer did well, but the rays were powerless to influence the resulting scars. A few cases of hypopyon ulcer were treated, mostly along with general light baths. Phlyctenular ulcers do so well with general light baths that it is rarely necessary to employ the local treatment in addition. A few cases of chronic conjunctivitis, chronic blepharitis, and trachoma were treated with benefit. In these cases the reaction is not so easily produced as in the skin, and much longer exposures were necessary. These papers, together with the recent symposium on the subject at the Oxford Ophthalmological Congress, do much to establish the claim of ultra-violet therapy to be a new method of great promise, but they also emphasise the existence of dangers and the necessity of entrusting the administration of the remedy to specially skilled hands alone.

TRAFFIC IN NARCOTIC DRUGS.

IMPORTANT information in regard to measures for the international control of the traffic in drugs of addiction was vouchsafed in the last report made to the Council of the League of Nations by the Advisory Committee dealing with that subject. It seems probable that the Opium Convention, signed at Geneva in February, 1925, which was intended to provide a central control board and thereby strengthen Chapter III. of The Hague Opium Convention of 1912, may become operative by the end of the present year. The Convention of 1925 was the outcome of the prolonged and acrimonious "Second Conference" at Geneva in 1924–25, from which the American and Chinese delegates felt compelled to withdraw. By its articles it could not come into force until ratified by ten of the Signatory Powers, including seven of the States represented on the Council of the League of which two must have permanent seats on that body. The Advisory Committee, in its last report, stated that 15 States in all had then ratified, including four which are members of the Council, two of them, Great Britain and France, being permanent members. It is anticipated that Canada, Japan, Netherlands, Switzerland, and Roumania will shortly deposit their instruments of ratification, and thus the requisite conditions for putting the Convention of 1925 into operation will have been achieved.

It is hoped by the Advisory Committee that when the Central Control Board, as provided by the Convention is set up, the highly unsatisfactory position of the illicit traffic in dangerous drugs, described as "enormous," will be checked. The report states that—

> "the seizures effected in various countries, particularly in the Far East, still represent considerable quantities; a return—incomplete owing to the inaccuracy of the figures given for certain seizures and relating to a period of about 18 months—shows the striking figures of 2320 kilogrammes for cocaine, 1600 kilogrammes for morphine, and 1150 kilogrammes for heroin, quite apart from a considerable number of seizures of which no precise details are given, but which represent totals perhaps as large as those given above. Moreover, it must not be forgotten that the largest proportion of the narcotics illicitly distributed escapes seizure."

The Committee are at a loss to know the sources from which the illicit traffickers draw their supplies of morphine and of the opium from which the alkaloid is derived.

It will be remembered that M. Zahle, the President of the Conference which drafted the Geneva Convention of 1925, stated that:—

> "if manufacture and transit (of drugs) have been well cared for, the same cannot be claimed for production. The American principle for a limitation of production to medical and scientific purposes, though accepted as a principle by the Advisory Committee on the traffic in opium and the Assembly, has not been included in the Convention as a contractual obligation," and "similarly only a limited progress can be claimed as regards the smoking of opium in certain Pacific countries."

It was omission to deal adequately with these aspects of the problem that led to the withdrawal from the Geneva Conference of the American and Chinese delegates, since they regarded the new agreements as derogating from the spirit and true intent of The Hague Opium Convention of 1912. While it is to be hoped that the expectations of the Advisory Committee, based on the coming into operation of the exclude the technical expert in health, housing, or agriculture? The Scottish Members of Parliament who object to the Bill have pointed out that there is no allegation of existing inefficiency; they have specially praised the administration of the boards which deal with health, agriculture, and prisons: they maintain that the proposals mean the denationalisation of Scotland and will hasten the advent of home rule. On this wider issue of autonomy and national sentiment Scotland will find support from the Welsh Members of Parliament who have lately been protesting against the proposed reorganisation of the Welsh Board of Health. To the latter the Minister of Health has replied that the abolition of a chairman and the reduction of the Welsh Board from four to three members is not part of a policy of denationalisation; the Board has not been an executive body; it has met not more than 28 times in the past nine years; its work is done by individual members in their individual capacities; the present change is a matter of internal administration only, a question of personal arrangements. This question of personal arrangements arises also in the Scottish proposals. The existence or the near prospect of certain vacancies has caused the administrative changes to be pressed forward now at a moment when they can most smoothly be effected. Sir John Gilmour appears to have given some kind of assurance that he will hold himself as accessible to his technical advisers as heretofore, though he frankly maintains that experts must be controlled. We do not, he observed, allow the military and naval experts to carry out all they desire. Similarly, "if the medical man had his way, he might possibly impose upon Parliament and the country a system eminently desirable no doubt but so extravagant or so much in advance of the time that Parliament could not tolerate it." Sir John Gilmour's best argument is that every inquiry and commission which has examined the science of administration has recommended the change he proposes. England has a Board of Admiralty and a Board of Inland Revenue; she has a Board of Trade (of which the Archbishop of Canterbury is a member amongst others), but fortunately this Board can act with a quorum of one member. Apart from these instances, this country has usually adopted the system of ministries and departments, administered under a single permanent head, and in recent years Northern Ireland has found it worth while to copy the same model. Board or Department—it is not the label that matters but the sympathetic intelligence which the Scottish Office will no doubt continue to supply.

INDICAN IN THE BLOOD.

IN 1924 C. H. Andrewes described in our columns[1] a new colour reaction which occurred on adding van den Bergh's diazo-reagent to the serum of patients with uræmia. His observations have been confirmed by other workers, and the test has been found of use in helping to diagnose the condition of renal failure. Andrewes failed to discover the nature of the substance which gave this reaction, but recently G. A. Harrison and R. J. Bromfield have shown[2] that the colour is given by an indoxyl compound presumed to be indican, which is potassium-indoxyl-sulphate. Indoxyl is formed in the body from tryptophane, one of the principal amino-acids in the protein molecule. The amount of indoxyl which is formed depends partly on the quantity and nature of the protein which is eaten, partly on the nature of the bacterial flora of the intestines. The indoxyl which is absorbed from the intestines combines (in the liver) with sulphuric acid, and the resulting indican is then passed on into the blood. If the kidneys are functioning properly, the amount of indican circulating in the blood is very small as it is excreted in the urine. The amount in the blood depends on four factors—namely, the quantity of tryptophane in the diet, the nature of the bacterial flora, the efficiency of the liver, and the efficiency of the kidneys. It has been found that the diazo-colour reaction runs roughly parallel with the concentration of urea and creatinine in the blood of uræmic patients, although the test occasionally proves negative. F. S. Patch and I. M. Rabinowitch[3] claim that in urological cases the diazo-test enables them to judge whether the excess of urea is of serious importance or not. This claim may have to be reconsidered now that the cause of the colour reaction is known to be indican, since in spite of gross renal damage, indican may not be present in excess in the blood owing to the failure of one of the factors necessary for its formation. Harrison and Bromfield are to be congratulated on their success in elucidating the cause of a colour reaction given by so complex a fluid as blood.

A FORGOTTEN RED CROSS PIONEER.

THE recent centenary celebration of the birth of Henri Dunant has stimulated the memory of Ferdinando Palasciano, surgeon to the army of the Neapolitan Bourbons, and his courageous advocacy of mercy to the wounded on the field of battle. From an account of his career by Prof. Cesare Baduel, director of the Italian Red Cross, we learn that Palasciano was early conscious of his responsibilities to soldiers, not only when they were effective combatants, but also when they were suffering and abandoned on the field of battle. At the present time it reads strange that, during the Sicilian insurrection against Bourbon rule in 1848, General Filangieri, who was besieging Messina, gave orders that no quarter was to be given to the enemy. Palasciano disregarded these orders and cared for the wounded of both sides. For this act of insubordination he was threatened with death, and he had to spend a year in prison as a reward for his clemency. Filangieri's persecution of Palasciano would doubtless have been more brutal had not King Ferdinand known him personally and valued him both as a man and as a scientist. In January, 1861, he offered to the Accademia Pontaniana at Naples a prize of 100 ducats for the best 100 rules of military surgery for the treatment of gunshot wounds. The prize was not awarded at first, but it was won some time later by Dr. Appia, of Geneva, and the Italian, De Vita. In connexion with this competition Palasciano declared before the Accademia Pontaniana that "belligerent powers, in their declaration of war, must recognise reciprocally the principle of the neutrality of the wounded and seriously ill, for the entire period of their treatment." He insisted that the principle of the neutrality of the wounded should be accepted, either by the ruling of an international congress, or by a special agreement between the belligerent powers inserted in the declaration of war. Five of his points were: (1) That the armies should be obliged to exchange wounded prisoners immediately after a battle. (2) All soldiers who were too severely wounded to be transported should be treated on the field of battle by the army's own sanitary service. (3) A sanitary staff, sufficient to care for wounded men in hostile territory, should be given a safe conduct and escort, and be allowed to remain until their task was finished, when, during a truce, the personnel could return to their own advanced post or to the frontier of the enemy's country. (4) All necessary food, lodging, and drugs should be provided by the Commissariat on the signature of the attending surgeons and on the assumption that reimbursement should be effected after the war. (5) In the case of sieges, and in addition to the exchange of the wounded, the besieged army should be allowed to send its wounded to any neutral country willing to receive them if the besieging army would not do so. In 1862 Henri Dunant published his "Souvenir de Solferino," which did so much to pave the way for the international conference of 1863. The International Convention, signed in August of the following year, neglected the fate of the fixation of dropped organs and for closing defects in the dura mater, and it can even be grafted into a hole in the wall of a hollow viscus. In some of these operations success is the rule, but in others it cannot be assured as yet. Further study will determine the conditions essential for a favourable outcome; nevertheless, much knowledge has already been gained, and the way has been pointed out for future inquiry into a method which has already proved to be a valuable asset in the hands of the general surgeon.

HEALTH CONGRESS AT PLYMOUTH.

SOME 850 delegates, including representatives of the Home Government, the Governments of India and the Dominions and of foreign countries, and a large number of members, making up a total of about 1500 persons, have assembled for the thirty-ninth Congress of the Royal Sanitary Institute, which bids fair to equal in success any of its predecessors. The Bishop of Plymouth preached at a special service in St. Andrew's Church on Sunday morning and the Rev. T. Wilkinson Riddle at George-street Baptist Chapel in the evening. On Monday the members and delegates were welcomed by the Mayor (Councillor W. H. J. Priest), who later opened the Health Exhibition at the Drill Hall. At 5 P.M. the inaugural meeting of the Congress was held in the Guildhall, when Prof. Bostock Hill, chairman of the council, in inducting the President, the Right Hon. Viscount Astor, referred to the many outstanding services which he had rendered to the advancement of hygiene, notably with respect to the fight against tuberculosis, the improvement of the milk-supply, and maternity and child welfare. Lord Astor's presidential address was an extremely interesting survey of the whole problem, but was much more in that it contained many suggestions and expressions of opinion likely to stimulate discussion when the meetings of the sections and conferences take place. Parliament, he said, had tackled the smoke nuisance in a timid manner, and he hoped some day they would be bold enough to deal with the domestic chimney. Our greater use of water might make it necessary to appoint, even at this late period, conservancy boards for all our rivers. He deplored the effect on birds and possibly on fish from the pollution of the sea by oil from ships. He hoped the time was not distant when the buyer would know whether he was buying raw or pasteurised, clean or dirty milk. He welcomed the more important status given to veterinary hygiene. He referred to the great benefit likely to accrue to industrial hygiene from the work of the International Labour Office at Geneva, the first section of the League of Nation's headquarters to become a going concern. After referring to the lamentably high maternal mortality and morbidity from childbirth, he expressed his views on the right and the wrong kinds of birth control. In urging the imperative need for the preservation of the beauty of the countryside, he suggested that local authorities should plan for new villages and try to keep the intervening spaces open. Practical schemes were possible by which owners of land deprived of building value could be compensated from the increased value of land that is developed. He expressed his disapproval of the recent proposal for the compulsory detention and treatment of men and women suffering from venereal disease. Regulations based on a low conception of human morality could not accelerate physical or moral progress. His concluding note was on the interrelationship of rest, harmony, and health, and a plea for a daily brief period of rejuvenating peace and constructive silence to counteract the excessive restlessness of modern existence. In moving a vote of thanks to Lord Astor, Mr. Ramsay MacDonald referred to the last portion of the address as "crammed full of shining wisdom." In this period of extraordinary evolution of science and power, it was very necessary that there should be some guiding principles, and that we should take stock and "consider the end of it all."

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXXV.

TREATMENT OF ACUTE AND CHRONIC LARYNGITIS.

ACUTE laryngitis is usually the result of an acute infection of the upper respiratory tract, a "cold," tonsillitis, influenza, or, in children especially, one of the exanthemata, notably measles. It is sometimes traumatic, due to inhalation of dust, irritating gases or fumes, or the accidental swallowing of caustic or very hot fluids; this latter accident occurs when children drink from a kettle.

Acute Laryngitis in Adults.

The treatment of acute laryngitis in adults presents a somewhat different problem from the treatment of a similar condition in infants. The adult patient should be kept in an even temperature, preferably in bed, and should be encouraged to drink large quantities of warm fluids. He may be given drugs to promote perspiration and to ensure rest—for example, aspirin grs. x., Dover's powder grs. viii. at night. Inhalations of steam impregnated with tinct. benzoin co., pine oil, or eucalyptus oil, every three or four hours for a quarter of an hour will be most useful. Abstinence from alcohol and smoking should be enjoined. Rest of the voice is important. Should cough be a prominent symptom a mixture containing small doses of heroin may be given. The attack usually subsides in a few days; the voice becomes normal, cough and secretion disappear. In rare cases œdema of the tissues over the arytenoid cartilages and of the aryepiglottic folds occurs. This results in dyspnœa of variable degree; it may be so severe as to demand tracheotomy. Should such a complication occur it is well to give antistreptococcal serum (25 c.cm.) subcutaneously, and a further dose the next day. Scarification of the œdematous areas has been advocated.

Acute Laryngitis in Infants.

Owing to the relatively small glottis, acute laryngitis in infants is apt to be more serious than in adults. Inspiratory obstruction is especially to be feared. It is essential to exclude diphtheria as the cause in a case of acute laryngitis. Diphtheria of the larynx is almost invariably accompanied by diphtheria of the pharynx, and will show itself by the presence of the typical greyish-white membrane on the tonsils and on the anterior pillars of the fauces or uvula; in all cases of doubt swabs should be taken from the pharynx. If the clinical examination give rise even to suspicion of diphtheria, the case must be given the appropriate dose of antidiphtheritic serum—for a child of 6, 8000 units, for a child of 12, 10,000 units—without waiting for the bacteriological report.

The general principles of the treatment outlined above must be adhered to for catarrhal laryngitis. Rest in bed in an even temperature is important, and since the child may not be able to inhale, a steam kettle should be used. Perhaps the most useful drug for children is chloral. It is of value mainly in ensuring rest, physical and mental, and in allaying the alarm that stridor produces; often merely keeping a child drowsy will enable tracheotomy to be avoided. Inhalation of oxygen through a nasal tube will be helpful. On the other hand, tracheotomy must not be too long postponed, since the child's heart will not tolerate too long the strain of dyspnœa; the patient's colour, the amount of "sucking-in," and the pulse must be considered in deciding on the necessity for tracheotomy or intubation.

Another disease that may be mistaken for laryngitis is laryngismus stridulus; this condition is one seen in rickety children, often associated with adenoids; attacks come on suddenly, generally

1925 Convention, may be realised, the larger question of the production of the raw material of the drugs in question remains to be dealt with, and is complicated by the fact that such producing countries as Turkey and Russia are outside the League, while other producing countries like Persia,[1] Greece, Bolivia, and Peru have not seen their way to supply the information asked for by the Committee.

FRONTIER NURSING IN KENTUCKY.

THE pages of THE LANCET open to-day with an address which Sir Leslie Mackenzie, until recently the Medical Member of the Scottish Board of Health, delivered in circumstances of wide medical importance, as well as of personal interest to the orator. The occasion was the dedication of a hospital and nursing centre, established by the Frontier Nursing Service of Kentucky in the eastern and mountainous regions of the State. The hospital is to serve as a main focus in an organisation for the prevention of disease and the maintenance and promotion of health in certain thinly peopled areas, which present a great similarity to the Highlands and Islands of Scotland in respect of the conditions which have to be met in providing medical service. And while the problems are similar, the methods of dealing with them are also similar, for the excellent reason that Mrs. Mary Breckinridge, the inspiring pioneer of the American work, commenced her task with a personal investigation in Scotland of the way in which the State and individual workers had dealt with the difficulties of the medical service in the Highlands and Islands. This Scottish area, as defined by statute, has a population of but 320,000 scattered over 10 million acres, either isolated by the sea or intersected by mountains and rivers which are impassable in many seasonal conditions. It is true that there is no marine peril connected with the medical service in Kentucky, but the mountains and rivers are there, and so are the scanty and poor inhabitants; and those responsible for the Scottish work may well be proud that their labours have found echo in the far West. We may hope that the activities in America will be attended with less practical difficulties than were those in Scotland through many long years of effort. The difficulties of transport and the needs of the two populations, though varying in detail, may be the same in significance, but the problems present in the scattered regions of the north of Scotland were much complicated by historic, racial and social differences which made any processes of amalgamation, for any purpose however worthy, extremely difficult of accomplishment. These things Sir Leslie Mackenzie sets out with the eloquence of one who not only was the leading spirit in dealing with them, but was born in the middle of them and knows their reality. Because of his intimate and personal knowledge both of the plight in which his humbler fellow-countrymen were, and of the great qualities demanded of those who undertook to minister to their medical needs, Sir Leslie, throughout his whole official career was a valuable servant of the State, of humanity, and of his calling. Therefore, he takes with him into retirement the thanks of all for what he has done, something of which is indicated modestly in his message to the Frontier Nursing Service of Kentucky.

THE MODERN VIEW OF EPILEPSY.

SUPERFICIAL observers are apt to remark that in spite of a vast amount of research we are as far as ever from understanding the cause of epilepsy. Those, however, who have personal experience of research in this disease know that such a statement betokens a lack of appreciation of the nature of the problem to be solved and hence of the means by which its solution will be accomplished. A military metaphor may here prove illuminating. In trench warfare an advance by one side can only occur after the preparation of vast quantities of munitions and a barrage by which the enemy's defences are broken down, but during this essential preliminary stage the position of the combatant lines remains unchanged. In the assault on epilepsy there is reason to hope that we are witnessing the preparatory barrage, and that though the lines at present remain stationary, much valuable work is being accomplished which is an essential preliminary to a true advance of knowledge. Reflections such as these are provoked by Dr. W. G. Lennox and Dr. Stanley Cobb's admirable review [1] of recent work on the condition. The authors confine themselves to the consideration of the mechanism involved in seizures, and the cause and treatment of epilepsy, rightly emphasising at the outset that epilepsy is a symptom and not itself a disease. The various physiological theories of the nature of a convulsion are critically examined, and the conclusion reached that no single theory can hold the field to the exclusion of the others. Considerable space is devoted to the pathological changes in the brain and elsewhere, which have been held to be related to epilepsy, but little stress is laid upon these. Much recent investigation of epilepsy has been biochemical, and about one-third of the review is a survey of this field, dealing especially with the significance of disturbances of acid-base equilibrium. Treatment is discussed, including starvation and a ketogenic diet. The number of references quoted is about 500, and Dr. Lennox and Dr. Cobb bring to bear upon this mass of material a judgment which is both critical and constructive, being based upon a wide personal experience of the clinical, experimental, and biochemical investigation of epilepsy. Their conclusion may be summarised in their own words, "the hope for an understanding of convulsions lies in a knowledge of the factors which affect the reactive capacity of nerve cells," and it is the multiplicity of such factors which renders the problem of epilepsy so complex and necessitates many and varied modes of approach. They are to be congratulated upon a work which will be a necessity to investigators of convulsive states and of practical value to all who have to deal with epileptic patients.

FASCIAL GRAFTING.

THE laws governing the transplantation of tissues are more or less known; it has been proved over and over again that grafting of fibrous tissue, if infection be prevented, is almost certain to be a success. But this knowledge does not seem to have been exploited to the degree its importance warrants. How far-reaching is the use of fascial grafting methods is brought home to the reader of two recent books, by Dr. Ernst König,[2] in Germany, and by Mr. H. C. Orrin,[3] in this country. In human surgery the fascial investment of the thigh has been chiefly used. It is convenient to obtain, and its removal does not lead to any detectable disability; it is of different thicknesses in its different parts, and is thus suited to various purposes; it can get its nourishment from the tissue juices which exude from the bed in which it is placed; it heals in and maintains its own proper structure; it does not shrink, and when subjected to strain it increases in strength. A simple enumeration of the uses to which it has been put will show how many and diverse are the conditions amenable to treatment by fascial grafting. Defects in tendons can be remedied in a way possible with no material which does not become an integral part of the organism; tendon sheaths can be replaced, and deformity resulting from a paralysed muscle can often be in part overcome by a transplant. Fascia can be used as a covering for the ends of bones in an arthroplasty or for winding round a nerve after suture; it is the best material for closing the aperture through which a large hernia has come; it has been used for the fixation of dropped organs and for closing defects in the dura mater, and it can even be grafted into a hole in the wall of a hollow viscus. In some of these operations success is the rule, but in others it cannot be assured as yet. Further study will determine the conditions essential for a favourable outcome; nevertheless, much knowledge has already been gained, and the way has been pointed out for future inquiry into a method which has already proved to be a valuable asset in the hands of the general surgeon.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXXV.

TREATMENT OF ACUTE AND CHRONIC LARYNGITIS.

ACUTE laryngitis is usually the result of an acute infection of the upper respiratory tract, a "cold," tonsillitis, influenza, or, in children especially, one of the exanthemata, notably measles. It is sometimes traumatic, due to inhalation of dust, irritating gases or fumes, or the accidental swallowing of caustic or very hot fluids; this latter accident occurs when children drink from a kettle.

Acute Laryngitis in Adults.

The treatment of acute laryngitis in adults presents a somewhat different problem from the treatment of a similar condition in infants. The adult patient should be kept in an even temperature, preferably in bed, and should be encouraged to drink large quantities of warm fluids. He may be given drugs to promote perspiration and to ensure rest—for example, aspirin grs. x., Dover's powder grs. viii. at night. Inhalations of steam impregnated with tinct. benzoin co., pine oil, or eucalyptus oil, every three or four hours for a quarter of an hour will be most useful. Abstinence from alcohol and smoking should be enjoined. Rest of the voice is important. Should cough be a prominent symptom a mixture containing small doses of heroin may be given. The attack usually subsides in a few days; the voice becomes normal, cough and secretion disappear. In rare cases œdema of the tissues over the arytenoid cartilages and of the aryepiglottic folds occurs. This results in dyspnœa of variable degree; it may be so severe as to demand tracheotomy. Should such a complication occur it is well to give antistreptococcal serum (25 c.cm.) subcutaneously, and a further dose the next day. Scarification of the œdematous areas has been advocated.

Acute Laryngitis in Infants.

Owing to the relatively small glottis, acute laryngitis in infants is apt to be more serious than in adults. Inspiratory obstruction is especially to be feared. It is essential to exclude diphtheria as the cause in a case of acute laryngitis. Diphtheria of the larynx is almost invariably accompanied by diphtheria of the pharynx, and will show itself by the presence of the typical greyish-white membrane on the tonsils and on the anterior pillars of the fauces or uvula; in all cases of doubt swabs should be taken from the pharynx. If the clinical examination give rise even to suspicion of diphtheria, the case must be given the appropriate dose of antidiphtheritic serum—for a child of 6, 8000 units, for a child of 12, 10,000 units—without waiting for the bacteriological report.

The general principles of the treatment outlined above must be adhered to for catarrhal laryngitis. Rest in bed in an even temperature is important, and since the child may not be able to inhale, a steam kettle should be used. Perhaps the most useful drug for children is chloral. It is of value mainly in ensuring rest, physical and mental, and in allaying the alarm that stridor produces; often merely keeping a child drowsy will enable tracheotomy to be avoided. Inhalation of oxygen through a nasal tube will be helpful. On the other hand, tracheotomy must not be too long postponed, since the child's heart will not tolerate too long the strain of dyspnœa; the patient's colour, the amount of "sucking-in," and the pulse must be considered in deciding on the necessity for tracheotomy or intubation.

Another disease that may be mistaken for laryngitis is laryngismus stridulus; this condition is one seen in rickety children, often associated with adenoids; attacks come on suddenly, generally at night, when the child wakes in distress with inspiratory crowing. The history of previous attacks, the absence of local pharyngeal signs of inflammation, and the type of child will help in arriving at a diagnosis. Retropharyngeal abscess, especially if low down at the level of the epiglottis, gives rise to dyspnœa; inspection with a good light from a forehead mirror or better, palpation with the finger will reveal a swelling of the pharyngeal wall and decide the diagnosis.

Recurrent Cases.

Should acute catarrhal laryngitis recur, predisposing factors must be sought in the upper respiratory tract and, if possible, removed. Any cause of nasal obstruction, especially a deflected septum, large middle turbinals or adenoids should be excluded; also foci of infection, suppuration in the accessory nasal sinuses, and inflamed adenoids or tonsils.

Chronic Laryngitis.

Chronic laryngitis may be the result of attacks of acute laryngitis; in this case it is all the more important to search for and remove the predisposing causes enumerated above. Treatment of the condition itself is partly general and partly local. Rest of the voice is essential. Faulty methods of voice production in singers or speakers should be corrected, and abstinence from alcohol and tobacco enjoined. A mixture containing potassium iodid grs. iii., pot. nitrate grs. x., oxymel ʒii., tinc. camp. co. ♏xxx., and extract ipecacuanha liq. ♏i. is useful. Locally, in established cases, painting the cords with a solution of zinc chloride (grs. xv. or grs. xx. to ʒi.) daily might be tried. In all cases of chronic laryngitis it is essential to exclude the possibility of tubercle by expert examination of the chest and sputum.

Syphilis as a cause must be excluded by a Wassermann test.

Atrophic Rhinitis.—There are one or two varieties of chronic laryngitis which call for special treatment—for example, that due to or secondary to atrophic rhinitis. Even vigorous treatment of the nose, set out below, may fail to cure the laryngeal disease, but should be patiently undertaken; the nose is to be syringed twice daily by means of a Higginson's syringe with a pint of normal saline, to which is added ℥ss. of carbolic acid 1 in 20—this will wash away crusts and keep the nasal passages clean.

Singer's nodules consist of small projections from the edges of the vocal cords at the junction of the anterior and middle thirds. Over-use or mis-use of the voice may be the cause, and must therefore be corrected. Failing this the nodes may be touched with the galvano cautery; this can be done by means of a specially shaped cautery point after painting the larynx with cocaine.

Pachydermia laryngis is a very resistant form of chronic laryngitis, in which there are projections in the posterior commissure or posterior parts of the cords. Removal of these projections has been practised in various ways with poor result. Recently, however, a degree of success has been obtained by the judicious use of diathermy (Kisch); under chloroform anæsthesia two or three punctures are made into the projections with a fine diathermy needle, and very considerable improvement has followed.

Tuberculous laryngitis is always a serious complication of phthisis, and the prognosis grave. Strict silence over a period up to three months will cure slight cases, when combined with general open-air treatment. More serious advanced cases may be arrested by the same means. Should the lung affection clear up local treatment of laryngeal swellings by galvano-cautery puncture under local anæsthesia is very useful. Advanced cases, in which pain is the prominent symptom, must be treated symptomatically by means of local insufflation of orthoform and anæsthesia.

ON THE NEED FOR STANDARDISATION IN CLINICAL PATHOLOGY.

The Opening Address to the Association of British Pathologists.

BY SIR THOMAS HORDER, BART., M.D. LOND.

DOUBT has been expressed in certain quarters as to the need for this Association. I have myself no doubts whatever on this score. In every branch of medicine there must of necessity be an academic side and a practical side. In anatomy, in physiology, in physics, in chemistry, there are men working out particular problems of an academic kind which, though they have a possible bearing, direct or indirect, upon the diagnosis and the treatment of disease, yet are conceived in a purely academic spirit and are pursued for their own sake and not as direct aids to the prevention or the cure of disease. It is so also in pathology. I suppose we are all members of the Pathological Society of Great Britain and Ireland, and are interested in the more abstruse problems that chiefly form the business of that body. But the doctor in charge of the patient could get very little pathological help in the conduct of his cases were he dependent directly upon the activities of that Society, however energetic these may be. There needs a special acquaintance with the particular aspects of disease, and experience of the material derived from the patient and how best to deal with it, in order to supply that important information which supplements clinical medicine and makes it a whole, rather than a part, of the disease-picture. Clinical pathology requires that the objectives constantly kept in mind are the diagnosis and the treatment of the diseased patient. Here, too, time is the essence of the contract. Pure research may be followed leisurely; indeed, to follow it in any other way than deliberately and slowly is to invite failure. Clinical pathology demands promptness and concentration towards an immediate practical end; the individual's health, perhaps life, is at stake, and this puts a limit to contemplativeness and abstraction. It is the application of pathological principles to practical medicine—it is not the discovery of those principles themselves—that we are concerned with.

The Unity of Pathology.

As to the importance of clinical pathology in our work as doctors it is no longer necessary to emphasise this. Time was when it was very necessary, and I am pleased to think that insistence upon the fact that the recent developments of medicine have been very largely in the direction of examining materials derived from the patient, rather than examination of the patient himself, is the fact to which I owe the honour of addressing you. This insistence, and the equal emphasis put upon the importance of preventing a divorce between pathology and clinical medicine, cover most of the small contributions which I personally can claim towards the progress of our science and art.

You will see, therefore, how reasonable it is that I should welcome the formation of this particular Association, consisting as it does of a body of men whose work lies very largely in this direction and—I speak quite deliberately—whose livelihood depends upon the important contributions made by them in their routine occupation towards the elucidation of the problem of the patient's disease and his treatment. I am quite certain that the Society has a great field, and I predict for it a very successful future.

Inasmuch as we are really all of us both clinicians *and* pathologists in spirit, though not in deed, I want to say a few things concerning matters that affect both sides of that science which we study from two different angles. I refer to the science of Pathology. For it must not be forgotten that Pathology remains the science of disease, and to study it without coming a great deal into contact with the patient in whom the disease is being expressed, is to deal with only one set of data and to leave an equally important set unconsidered. I like to preach the unity of pathological processes, because there are still some who speak and act as though the whole thing can be seen and dealt with, either in the laboratory or at the bedside, whereas it requires a study of both aspects of the problem to achieve a satisfactory view.

The Doctor's Brief to the Pathologist.

For this reason it is of great importance that you should get as full a brief as possible from the doctor *concerning the clinical features* of the case in which help is asked. For the present unsatisfactory position in regard to this desideratum both parties are a little to blame. One fact which tends to obstruct this very necessary liaison is the existence of laboratories in which the personal element as between doctor and pathologist is quite eliminated. Materials are dumped in these places much as coals are dumped at our houses. I supposed such places are necessary ; anyway they seem to have come to stay. I do not patronise them myself, because I am fortunate enough to be in frequent daily touch with colleagues working in pathological laboratories. But I am quite convinced, even apart from such facilities as I and all of us in large centres possess, that the commercialising of this part of our work is as bad for the patient and for us as it would be if clinical medicine were itself commercialised. When this matter is considered by the Association it might be well to hear the views of some practitioners. There is, by the way, another matter of policy which I suppose you will be discussing, and that is the vexed question of the supply of such therapeutic agents as vaccines from hospital centres. This is a large subject, and merits very full consideration before taking up a definite position. But I have no doubt that the Council, and the Association generally, realises the great importance of maintaining all the best traditions of our profession, and that they can be trusted to do this in connexion with these and with allied matters.

Again and again we see the futility of pathological work, and conclusions drawn from this, when it is a thing quite detached from the clinical aspects of the case. We are so familiar with this fact that to quote instances is superfluous. Recently a patient brought me her blood report. After detailing the figures and certain other observations the report stated that "this is most probably an anæmia of the Addisonian type in spite of the high Hb and low C.I. This group comprises P.A., sprue, and bothriocephalus anæmia. The eosinophilia, consisting of young eosinophils, makes the diagnosis of the last named tempting, though unlikely." Now as a matter of fact the patient had had her spleen removed six months ago, and was, at the time of this count, suffering from a severe attack of urticaria. Both of these facts were, of course, of the utmost significance, and in face of them the valiant efforts at explaining the blood picture became pathetically ludicrous when one saw the patient—a plethoric-looking woman with a red face, who has never been out of England.

This struggle to get farther than the data of the examination admit should be resisted, whether it be as regards diagnosis, or prognosis, or treatment. And since I have embarked upon the matter of pathological reports, with which, after all, my contact with clinical pathology is chiefly concerned in these days, I may as well say a few more things about them now they are in my mind.

The Logic of the Report.

It cannot too often be iterated that no amount of negative investigations ever establishes a positive diagnosis. At the most a negative report gives presumptive evidence against a certain condition or disease. In simple cases such as (say) the absence of a demonstration of T.B. in sputa, or of gonococci in urethral pus, we know how illogical it is to conclude that phthisis or gonorrhœa, respectively, is not present. Yet a more illogical conclusion is now and again perpetrated in the face of a set of negative data, more illogical because the tests conducted are relative tests and not absolute ones. I have more than once drawn attention to the occurrence of well-marked cases of typhoid and paratyphoid in which agglutinations are completely absent, and where the pathologist reports that this negative point excludes these diseases. Of course this is not so. But it not seldom happens that blood cultures, urine cultures, and even stool cultures also prove negative in such cases. When this is so, even pathologists of great experience are prone to consider themselves justified in excluding this group of infections, thus contravening a logical principle of a most primitive kind. The explanation of these cases is not at present forthcoming. It looks as though the present technique, thorough though it is, is not quite suited to them in some way. However this may be, I do, and not at all infrequently, see cases in which the clinical evidence of typhoid or paratyphoid—and I am often unable on clinical grounds to distinguish these infections with any degree of certainty—is quite indisputable ; a definite incubation period, an ingravescent pyrexia, a relatively infrequent pulse-ratio, headache, epistaxis, enlarged spleen, leucopenia, patulous belly, rose-spots, defervescence by lysis, and even one or two relapses ; *yet the serum agglutination*, and the most careful blood and stool cultures, may fail to yield any positive data. I have at home two pathological reports concerning such cases in which the sentence occurs : "Whatever this disease is, it is not in the T.A.B. group."

I am speaking on this point rather fully because it illustrates a principle to which I want to draw attention. There is in the minds of some pathologists an idea, never perhaps so baldly defined as I am now defining it, yet receiving frequent practical application, that facts ascertained in the laboratory have a different and a more trustworthy value than facts ascertained at the bedside. This seems to me to indicate lack of clear thinking. If a fact be clearly established it matters not in which sphere of observation it is found ; nothing can make it less, or more, a fact. We all realise, of course, that the clinical expressions of disease are more difficult to interpret than those revealing themselves to the more exact methods of the laboratory, but there are fallacies of a special kind in laboratory work, and there is need for forbearance in the use of the microscope and the test-tube, just as much as there is in the use of clinical methods. In the last resort we are all reduced to the exercise of our own judgment and our reason, and we are all equally prone to fall victims to authority and our own preconceived ideas. In proportion as we do fall victims to these things the complexities of disease are certain, sooner or later, to humiliate us, and bring us back to fundamental principles.

The Final Test is the Patient.

What is the final test in all such difficulties of reasoning and experience ? It must be the patient, of course, and what eventually happens to him. And only by maintaining a close liaison between clinical medicine and pathology can these doubts be settled. We are familiar with the expression "pathology as a help to clinical medicine." I was once bold enough to read a paper upon "Clinical Medicine as a Help to Pathology," and I should still like to commend this thought to the members of the British Pathologists' Association. There are still not enough consultations between clinicians and pathologists, and this refers both to hospital and to private practice. The bedrock of our work is the post-mortem room. It is there that our vanities get the shocks that are so good for them, but it is also there, I am glad to say, that our efforts get their best encouragement. We should see to it

Canada.—Dr. E. Gendreau (Montreal); Dr. Duncan Graham (Toronto); Dr. G. E. Richards (Toronto); Dr. Harold W. Wookey (Toronto).

India.—Prof. R. B. R. N. Bhatia (Lucknow); Maj.-Gen. B. H. Deare (Calcutta); Dr. H. M. Masina (Bombay); Mrs. R. Young (Delhi).

New Zealand.—Dr. Andrew Muir Begg (Otago); the Hon. W E. Collins (New Zealand).

Singapore.—Dr. J. C. Tull (King Edward VII College).

South Africa.—Dr. R. B. Denison (Univ. of South Africa); Dr. C. Louis Leipoldt (Univ. of Capetown); Mr. W. Welchman (Univ. of the Witwatersrand).

The King's Reply to the Address.

In the course of his reply to the address presented by Sir John Bland-Sutton, His Majesty said:—

"I note, with interest, that your object is research both into the cure and causes of cancer. No doubt, in the last resort, the discovery of the cause is the only certain and absolute means of cure. But I am glad that you have not ignored the practical side of the problem. Remembering the thousands of sufferers from cancer, I feel that if your discussions lead to advance in diagnosis, treatment, or even palliation of the disease, this Conference will have justified itself and earned the gratitude of mankind."

TUESDAY, JULY 17TH.

At the Royal Society of Medicine on Tuesday morning the **SECRETARY** read a letter of welcome from H.R.H. the Duke of York, and Sir **JOHN BLAND-SUTTON**, the President, said that students of nature recognised in the animal kingdom an innate rhythm which caused bees to swarm and animals to congregate. This rhythm had brought together to-day a hive of able men, all interested in a disease which, according to the lay press, threatened to exterminate civilisation. Out of this world-wide swarming of experts Sir John hoped that some valuable help would come. He welcomed especially the delegates who had come long distances and from overseas to assist in the conquest of cancer.

Lord **DAWSON OF PENN** presided at the discussion on

THE ÆTIOLOGY OF CANCER,

and emphasised the magnitude of the problem and the patience necessary for even the smallest advance. The discussion was opened by Prof. J. **EWING** (New York), who pointed out that two distinct problems must be considered: the exciting factor or causal genesis and the nature of the tumour process or formal genesis. Knowledge of the former was comprehensive and at times almost final, and the knowledge had proved fruitful both practically and theoretically. The other problem had made little progress, despite the modern weapons of biology, biophysics, and biochemistry; it seemed to await substantial advances in general science. The problems of the nature of cancer and of growth in general were probably identical. The exciting factors acted with predisposing causes, of which chronic irritation of any kind was the most significant. Some irritants excited a slowly progressive process which might not reach the stage of cancer for many years, and minute amounts might be sufficient. Bacterial causes were less well-defined than chemical and mechanical, but the process excited by the tubercle bacillus, might progress of its own momentum and gradually acquire neoplastic properties with complete elimination of the bacillus. Precancerous changes showed every transition stage from normal inflammatory to neoplastic overgrowth, strongly suggesting that the forces at work were merely the intrinsic powers of the cell. The changes were not, however, invariably present. The factors predisposing to irritation were tissue abnormalities and heredity. The idea of dedifferentiation of adult cells was unwarranted, and Hannsemann's conception of anaplasia was more applicable to malignant cells. The hereditary element seemed to be dominant in some forms of cancer and recessive in others, and was a structural or physiological peculiarity of the organs predisposing them to cancerous reaction.

The best explanation of malignant growth was the theory of cell autonomy, but this did not account for the persistent growth over long periods and the capacity for independent existence in metastases. The soundest field of modern research dealt with growth-stimulating substances in embryonic and tumour tissue.

Cancer a Multiple Disease.

The theory of a universal cancer parasite must be ruled out for lack of evidence, but micro-organisms might act as irritants. General physiology might throw more light on cancer than the detailed biochemical processes. That malignant growth was always essentially the same in its physical, chemical, and physiological relations was an unwarranted assumption, and studies aiming to solve the whole problem at one stroke were destined to fail.

Dr. F. **BLUMENTHAL** (Berlin) said that the cancer cell was a cell with new chemical properties which differed only quantitatively and not qualitatively from those of normal and embryonic cells. The totality of these changes led to the specific capacity of transmitting these properties to their posterity. Cancer stimuli proceeded by way of an inflammatory stage with increased cell division and regenerative processes; after this stage the cancer cell acted autonomously without stimulus. The stimulus could not be a universal cancer producer. Special and incidental cancer parasites were only significant in the pre-cancerous stage, and then only if they displayed a definite metabolism or acted as carriers of a cancer agent. This agent was probably a cellular product which, on the decay of cancer cells, was taken up by macrophages, so that they became cancer cells or transmitted the agent to others. This agent was therefore infective and could adhere to parasites inside the tumours and penetrate into healthy cells. It might be something like the bacteriophage; it might be a catalyst or an enzyme. Perhaps it originated in the monocytes in the spleen.

Prof. A. **LEITCH** (London) said that a similar tumour might be produced by quite dissimilar substances, and very dissimilar tumours might be produced by one agent. Experimental tumour production was always a slow process; it was not the age of the subject that mattered but the time of exposure to the noxious agent. In the early stages no morphological change could be detected, but the cell undergoing cancerisation might be said to be "accumulating growth substance." Some adult cells had entirely lost their growth substance; they could not regenerate and never formed tumours, but the majority retained a certain amount, and under sufficient stimulus the regeneration reaction passed into proliferation. Gye's claim to have isolated this growth substance as a virus could no longer be upheld, but it was possible to induce the filterable fowl tumour in the absence of a virus, and herein lay hope of future developments. This tumour was near enough to a sarcoma to suggest that the "growth substance" might be within the range of experimental investigation.

Dr. A. **BORREL** (Strasbourg) gave a lantern demonstration of his method of studying cancer cells in cover-glass cultivations stained by the methods used for ultra-microscopic viruses. They showed a remarkable density of coloration and development of the mitochondrial threads, filaments. and straight rods, sinking into an indefinite stained granulation spot which might be a symbiotic microbial spot. Between the cells were sometimes seen granulations like those of molluscum contagiosum. All the cancers resulting from parasites, scalds, X rays, syphilitic lesions, &c., appeared in a cellular system which he called the neuro-tropho-pigmentary system, in which all the parasites concerned lived and grew. The "cancer age" corresponded with the whitening of the hair, when the system became a phagocytic system causing the sclerosis and degeneration of old age. All the predisposing causes of cancer had an elective irritant action on the tropho-pigmentary system.

Prof. H. T. Deelman (Groningen) described the post-mortem findings in a patient who had died of pneumonia with a cancer of the pharynx appearing two years after operation for buccal epithelioma. The manner of growth of the pharyngeal tumour showed that a gradual centrifugal change of epithelium into cancer cells must have taken place. The case could only be explained on the old conception of inductive growth. It was possible to imagine some process similar to that of the trephones which played a part in the healing of wounds. A fruitful field for investigation would be this influence from cell to cell as displayed in leukoplakic epithelium.

The Filterable Agent in Chicken Tumours.

Dr. J. B. Murphy (New York) said that the real nature of the neoplastic "agent" was at last emerging. *Two striking facts indicated that* we had to deal with endogenous chemical substances rather than with extrinsic living viruses; these were the high degree of selectivity and the specificity of the types produced. The chicken-tumour agent was remarkably resistant to ultra-violet light and gave evidence of forming a chemical union with tissues of susceptible animals. Dr. Murphy described experiments to determine the nature of the tumour-inducing agents. The major portion of the resulting purified fraction seemed to consist of a nucleo-protein; it gave a uniform Feulgen reaction of the thymonucleic acid group and produced tumours in fowls with great regularity. It was impossible to believe that this fraction could carry through all its precipitations any living organism or virus, and its enzyme-nature seemed to be established. By similar technique a similar agent producing the typical tumour, transplantable in 90 per cent. of fowls, had been isolated from such tissues as the healthy testicles of normal fowls.

Metabolism and Cancer.

Dr. J. Maisin (Louvain) described experiments on the relation of metabolic disturbances and the appearance of experimental cancers. It had been found that copper and magnesium in suitable doses might delay the progress of cancer and diminish the percentage of metastases; and that nitrate of ionium, injected in large doses before tar-applications, reduced the time before the appearance of cancer and markedly increased the percentage of metastases. This salt also prevented the regression of tar cancers and transformed fowl embryomata into huge polymorphic-celled sarcomata. An albuminous extract of chick embryo accelerated cancer formation, while lecithins and nucleins from blood or chick embryo retarded it. The liver diet of Whipple and Minot and Murphy definitely accelerated the production of tar cancer. Ionium seemed to be capable of destroying vitamin A and modifying cholesterinæmia and glycæmia in rabbits.

Prof. Rhoda Erdmann (Berlin) described experiments showing tumour development in rats taking a diet over-rich in vitamins B and D. The process was one of constant change of the respiratory quotients of the body fluids. First of all only cells which grew with a low quotient multiplied, and formed endothelial and reticular irregularities; then, by a rise of quotient, the cells isolated by these irregularities had a chance to multiply. and so malignant growth might appear. Heart muscle cultivated (*a*) in the plasma of cancerous rats, and (*b*) in the plasma of rats fed on B- and D- deficient diets showed "excess fermentation" in both cases.

Prof. J. McIntosh (London) argued for the virus theory of cancer, and described work on the Rous tumour. He was convinced that the filtrates used were cell free and behaved in exactly the same way as filterable viruses.

Prof. Teutschlaender (Heidelberg) said that three equally important factors coöperated proportionately in the ætiology of cancer: the exogenous agent, the local and general disposition, and the exposition. If disposition preponderated, any stimulus might produce cancer; exogenous noxious agents only produced cancer in a healthy organism through pre-cancer stages, which were the expression of grades of disposition gradually created by the quasi-specific agents. Quasi-specific carcinogenic stimuli not only elicited cancer in a suitably disposed organism, but also created the necessary disposition in a healthy organism. Endogenous substances might have a similar action to that of the exogenous, the diversity and variability of which, and their varied results, proved that they were not the immediate causes. There must be some specific factor, which was undoubtedly endogenous and probably of ferment nature. The macrophage doctrine of this factor was not, however, satisfactory for carcinoma. The factor had been shown to be formed by chemical irritation in embryonal or embryonalised cells which were specially sensitive or sensitised to growth stimuli. The moment of origin of this factor was the critical moment; up till then the "pre-cancerous" state would last. Its formation was preceded by an increase in the permeability of the cell membrane, with consequent alteration in the ionic equilibrium and calcium-potassium coefficients. The problem was a problem of metabolism. "*Factors of exposition*" were all agents that afforded an opportunity for the action of exogenous stimuli, and might be governed by mode of life, occupation, or condition. From the point of view of practical prophylaxis the exposition was the most important factor and should be more carefully studied.

Prof. R. Bierich (Hamburg) described the influence of lactic acid, which was produced in greater quantities in tumour tissues than in normal, and was not immediately removed. Hence it suffocated cells with normal respiratory processes, and only those independent of oxygen could grow. It achieved such a concentration that it dissolved neighbouring cells and so caused malignant invasion.

Prof. Proust (Paris) said that the best hypothesis to explain the phenomena was that of a cell alteration which allowed penetration by cytotropic viruses. Normally these viruses circulated in the blood in a state of adsorption or attached to corpuscles.

THE RELATIVE VALUES OF SURGERY AND RADIATION IN TREATMENT.

Prof. C. Regaud (Paris) opened this discussion. He said that improved therapeutic results were due to advances in technique and knowledge of the use of short wave-lengths. Tumours varied considerably in their sensitivity to irradiation. "Epidermoid epitheliomata" were very sensitive, and could be cured selectively by doses which did not produce extensive radio-necrosis and which left the general tissues almost unaffected. They were the only epithelial cancers cured by radiation almost as a routine. Primary breast cancer was sufficiently sensitive to be cured, but the wide extent and the involvement of the blood-vessels, beside other reasons, made the treatment of election extensive amputation with axillary clearance. Rectal cancers were very radio-resistant; the rectal mucosa was almost as vulnerable as the neoplasm, and the anus gave a poor access. External radiation was useless and internal radiation uncertain. Extirpation was best, or failing that, colostomy, to rest the intestine and check infection of the cancer. Preliminary radiation probably did not affect the result, but rays gave a passing relief in the painful stage. Adenocarcinomata of the uterus, like other glandular cancers, were habitually incurable by selective short-wave radiation. The reasons for these differences in sensitivity were histophysiological; they depended upon the activity and rhythm of the divisions and on the secretory function. The healthy cervico-vaginal epidermis was very sensitive, but its destruction was soon repaired. The mucosa of the mouth, however, being constantly in use, was liable to become infected through denudation.

Cancer of the Cervix Uteri.

Dr. **Malcolm Donaldson** said that the difficulty of estimating the relative values of the two measures lay largely in the absence of reliable figures. Most surgeons were not interested in averages, but in individual patients, and the number of hospitals with follow-up departments was lamentably small. A further difficulty was that of comparison, of knowing which cases were "operable." Standards of cure varied; the five-year rate was not universal, and operability percentages were often calculated on the flimsiest evidence. Certain authorities had, however, obtained valuable results from onerous sifting of the evidence—e.g., Dr. Janet Lane-Claypon in this country, and Heyman, of Stockholm,[1] who gave the five-year survival rate of 3659 hysterectomies as 35·6 per cent., and of 145 cases treated by radiation at the Radiumhemmet as 46·2 per cent. The two treatments were probably equally efficacious in operable cases. Nevertheless the initial mortality from the surgical method was at least 10 per cent., but that from radiation was nil. The operation laid a patient up for two months; the irradiation kept them from work for a fortnight only, and was practically painless, so that patients were not nearly so afraid of it, and sought advice earlier. As a palliative measure in advanced cases it surpassed everything else, and it was bound ultimately to replace excision.

Dr. A. **Lacassagne** (Paris) said that the four factors governing the results of radiation in uterine cancer were the extent of the disease, the quality of the treatment, the histology of the tumour, and the associated infection. They were extremely variable, and the essential condition of success was correct technique. When this was satisfied, the chances of cure of an epitheloma were practically the same whatever the local extent of the disease or its histological variety. This did not, of course, apply to adenocarcinomata. The frequency of associated infections necessitating suspension of the treatment, and of local anatomical changes interfering with it, increased with the extent of the growth.

Dr. W. P. **Healy** (New York) analysed a series of 224 cases, and showed slides demonstrating his classification of epidermoid carcinoma of the cervix into three groups according to their degree of anaplasia, which corresponded closely to their malignancy and radiosensitivity. The success of radiation depended on the promptness of the treatment and the sensitivity of the tumour; surgical success depended on early diagnosis and a low degree of malignancy. Radiation gave better results than surgery in carcinoma of the cervix, without the operative mortality.

Dr. **Max Cheval** (Brussels) described his method of irradiating deep-seated tumours by means of a projection apparatus containing four grammes of radium element. This was applied over large fields in preference to the multifocus method. The very penetrating γ rays caused no disturbance of the general health nor anæmia, wherever they were applied. Thirty-five patients with tumours of the larynx and base of the tongue had been successfully treated, and no necrosis was observed. Large fields would supersede other methods as extended operation had superseded parsimonious excisions. Good results had also been obtained on tumours in other parts of the body, but unfortunately no statistics were yet available.

Dr. E. H. **Zweifel** (Munich) showed tables of collected statistics of the results of X ray and radium treatment of cancer of the uterus. The percentage of cures (five years or more) in a series of 3770 was 16·8, which corresponded roughly with the surgical results. In 1629 inoperable cases, however, the percentage of cures was 11·3. Combined operation and radiation should be practised more often; radiation was valuable both before and after excision.

Dr. J. **Muir** (New York) gave an account of the evolution of the platinum radon seed, which was especially useful for inaccessible lesions.

Mr. **Comyns Berkeley** summarised the results of 616 cases operated upon by himself and Mr. Victor Bonney. The combined immediate mortality was 17 per cent. A surgeon's operability-rate must in fairness be calculated on all the patients he ever saw, in private practice as well as in hospital, and in wards other than his own. The rush of patients to the Middlesex Hospital had made an accurate calculation impossible, but his approximate rate now was only a little lower than the 63·5 per cent. of the early years during which he had used the radical operation. The mortality-rate was a matter of luck; he had had 60 cases without a death and then 9 deaths out of 18; 52 per cent. of his cases had been in Group III., the "query operable" group of continental surgeons.

Of his 616 cases, 276 had had carcinomatous and 340 non-carcinomatous glands. The immediate mortality in the former group was 20·6 per cent., as against 12 per cent. in the latter. Of 517 patients 240, or 46·4 per cent., survived after three years; of these 36 per cent. had had carcinomatous glands removed. At the end of five years 36·8 per cent. survived, of whom 37·8 per cent. had had carcinomatous glands. Whatever the effect of radium would have been on those without glands, it was a matter for speculation whether the 37·8 per cent. with gland involvement would have been alive to-day.

Mr. **Victor Bonney** condemned current methods of classification, and pleaded for the simple statement by radiologists of the number of cases treated and the number surviving after five years, to allow comparison between radium and surgery. It might be useful to see if certain classes were benefited by one treatment rather than another. Five years was not long enough, and the minimum period should be ten. His own figures, up to the end of 1926, were 332 cases with an operative mortality of 16 per cent.; 137 had died from recurrence. Of the 100 patients surviving with whom he was in touch, 64 had completed five years. Including six who had died and 17 who had been lost sight of (all after the five years), the total of survivors after that period was 87, and 51 were alive and well after ten years or more.

Cancer of the Rectum.

Sir **Charles Gordon-Watson** described the method of applying radium from behind by the open perineal route, after removal of the coccyx and division of the junction line of the levatores ani. The vagina was an important auxiliary avenue of approach. An important feature of this method was its attack on the lines of lymphatic spread. For growths extending above the peritoneal reflection the intraperitoneal route was used. Distant radium therapy, from a wax shield moulded to the perineum, would, he thought, prove especially valuable for squamous-celled carcinoma involving the anus. Radiation would probably be found a useful preliminary to excision, and should be used as an accessory to excision to attack glandular enlargement in the lower pelvic meso-colon. Deep X ray therapy on 17 cases of advanced imoperable disease had proved disappointing. Out of Sir Charles's first 15 cases, two were well to-day and one had been cured but had died of intra-peritoneal hæmorrhage on closing the colostomy. Of recent cases several gave promise of cure: time was too short to speak definitely. The radical operation would cure cancer of the rectum in all but the very young, if the patient would consent to colostomy. Until the use of radium became more certain, it was the duty of the profession to advise radical surgery whenever possible, but radium would cure and alleviate more inoperable cases every year.

Mr. W. E. **Miles** pointed out that direct spread of rectal cancer was comparatively slow; venous spread was so rare as to be negligible, but dissemination through the lymphatic system was all-important. Dissemination by the extra-mural system was much more widespread and serious than by the intramural, and the upper zone of spread was more important than the middle and lower. Cancer spread from the rectum chiefly through the ischiorectal fat, the levator ani muscles, the pelvic peritoneum, and the pelvic mesocolon. He had abandoned the perineal operation in 1906, because it had failed to include this upward zone, and had substituted the abdomino-perineal method, from which the recurrence mortality had been 30 per cent. only, in over 300 cases. The operation mortality had steadily decreased.

---

[1] Acta Radiol., 1927, viii., 363.

Mr. J. P. LOCKHART-MUMMERY dismissed radium treatment as unsatisfactory. Of 117 private cases treated surgically, the operation mortality had been 3·4 per cent., and in 242 hospital cases it had been 8·6 per cent., although a large number of the patients were over 70. Of 130 operated on over five years ago, 57 had been "cured," 57 had recurred, 8 had died from other causes, and 8 were untraced. Analysis showed that in picked cases the chance of cure was 66·6 per cent., and that even bad cases with intensive involvement were well worth operating upon. Liability to recurrence was extremely variable. Of 50 patients traced beyond the five-years' period, seven had died of recurrence in the sixth year, but none after that.

Dr. DOUGLAS QUICK reported the results of radiation treatment of 710 inoperable and for the most part hopeless cases. Only 150 were living at present; of these 18 were free from disease after 3–8 years, 17 between one and three years, and 10 under a year.

Middlesex Hospital Dinner.

A dinner in honour of the delegates to the Conference was held at the Savoy Hotel on July 17th at the invitation of the Middlesex Hospital and Medical School. Prince Arthur of Connaught presided. After the loyal toasts had been honoured, Mr. E. L. Pearce Gould, the Dean of the Medical School, proposed "Cancer Research." He commemorated the far-sighted generosity of Samuel Whitbread, whose portrait appeared on the menu card and who 136 years ago had given to the Middlesex Hospital its first ward set aside for incurable cases of malignant disease. The success of the Middlesex was due to the uniting under one management of the general hospital, the medical school, and the research laboratory, thus coördinating the whole of cancer research—pathological, biological, radiological, and statistical. The growing sense in the public mind of the seriousness of the problem, the quicker diffusion of knowledge and the higher standard of medical and scientific training, made it possible to prosecute research with good hope of success. Progress might be slow, but those who believed did not make haste. Prof. H. T. Deelman, of Groningen University, replying, described the account he had recently read of a fatal case of malignant disease recorded by a clever physician 300 years ago. Three hundred years hence men would either look on cancer as an historical curiosity or pity us for our ineffectual ways of dealing with it, but they would reap the benefits of our present labours. He paid tribute to English initiative and energy in research. Prof. Raffaele Bastianelli, of the University of Rome, praised the impulse that the Middlesex Hospital had given towards the attack on the cancer problem, and prophesied for it a great future. The health of the Guests was proposed by Mr. W. Sampson Handley and responded to by Prof. C. Regaud, Director of the Institut du Radium in Paris, and Prof. James Ewing, of Cornell University. Sir John Bland-Sutton proposed the health of the Chairman. The party consisted of some 180 hosts and guests and formed a happy occasion for the reunion of workers in many different lands.

SURREY COUNTY HOSPITAL.—This institution, at Guildford, is to be enlarged by the addition of 52 beds. The extension has become necessary largely by reason of the number of motoring accidents.

SHEFFIELD SCHOOL OF MEDICINE.

CENTENARY CELEBRATIONS.

LONG before the University of Sheffield was constituted in 1905 its medical faculty was in existence as the Sheffield School of Medicine, whose history was briefly told in our issue of July 7th (p. 26). The celebrations on July 11th marked the centenary of this school's foundation and testified to its importance in the progress of medical education among the provincial centres of this country.

The proceedings opened in the Firth Hall of the University with an address by the Chancellor, the Marquess of Crewe. In welcoming the delegates from other universities, faculties, and schools of medicine, Lord Crewe mentioned an address delivered 20 years ago by the late Sir Clifford Allbutt, and quoted a phrase which he considered one of the clearest he had ever heard on the function of a university: "the great value of a university education lies in the fact that the students come into contact with and see real research work actually being carried on." This, and the free exchange of ideas which could only occur in an atmosphere of "live work," were, he thought, the most valuable parts of a university education.

Sir Farquhar Buzzard, Regius Professor of Medicine in the University of Oxford, in his reply to the Chancellor, spoke of the fraternal feeling between the old and the new universities, and said that it seemed strange to find a parental university which had only just attained years of discretion watching a member of its school-room celebrate its hundredth birthday. He briefly sketched the early life-struggles of the school.

Sir Humphry Rolleston, Regius Professor of Physic in the University of Cambridge, also referred to the early years of the school. The birth of an institution, like that of an individual, was, he said, by no means painless, but in spite of the difficulties attending its birth, the Sheffield School of Medicine had grown into a very vigorous and flourishing offspring of which the University was justly proud. His own University, he said, owed a great deal to Sheffield, which had sent them that great classic Henry Jackson, and those of his colleagues who knew Henry Jackson wished him to express this feeling and to congratulate the staff of the Sheffield Medical School, whose first whole-time professorship of anatomy was founded by the widow of Arthur Jackson, Henry's brother, to perpetuate the memory of her husband. No history of the Medical School of Sheffield could be written, went on Sir Humphry, without an account of the invaluable services rendered to it by the present professor of medicine, Dr. Arthur J. Hall, who by his unselfish devotion and inspiring influence, poured out for 40 years, had undoubtedly done more for the school than any other single individual. During these 40 years Prof. Hall had held and resigned two previous professorships, those of physiology and pathology, and the invaluable Pathological Museum of the University was almost entirely due to his personal efforts.

Prof. J. Sholto Douglas, Dean of the Faculty of Medicine, then presented to the Chancellor the various delegates, several of whom had been personally connected with the University in its earlier days, notably Sir John Robertson, who was professor of bacteriology, in 1898, and medical officer of health for Sheffield, and Prof. J. S. Macdonald, who was the second whole-time professor of physiology, being appointed in 1902 and holding the chair till 1914, when he returned to Liverpool to succeed Prof. Sherrington. The following delegates were received:—

University of Birmingham, Sir John Robertson; University of Bristol, Prof. Edward Fawcett, F.R.S.; University of Cambridge, Sir Humphry Rolleston; University of Dublin, Prof. Joseph W. Bigger; University of Durham, Sir Thomas Oliver; University of Edinburgh, Prof. G. M. Robertson; University of Glasgow, Prof. John Glaister; National University of Ireland, Patrick Bennett; University of Leeds, Prof. J. Kay Jamieson; University of Liverpool, Prof. J. S. Macdonald, F.R.S.; University of London, Sir Holburt Waring; University of Manchester, Prof. H. S. Raper; University of Oxford, Prof. Sir Farquhar Buzzard; University of Wales, Prof. A. W. Sheen.

Prof. J. B. Black, the Public Orator, then presented Dr. H. H. Dale, F.R.S., Prof. A. J. Hall, Sir Frederick Gowland Hopkins, F.R.S., and Sir Thomas Lewis, F.R.S., for the honorary degree of Doctor of Science. Having conferred these degrees the Chancellor declared the Congregation closed, and Sir F. Gowland Hopkins offered the thanks of the new graduates for the honour paid to them.

The Faculty's Luncheon.

After the Congregation a luncheon was held at the Royal Victoria Hotel, attended by a large gathering of old Sheffield students. Besides the honorary graduates and delegates, the Lord Mayor and Master Cutler were the guests of the Faculty of Medicine, whose chairman, Prof. A. J. Hall, presided over the gathering.

After the loyal toasts had been honoured the Chancellor of the University rose to propose "the Faculty of Medicine." He referred to the close association between the civic authorities of the city and the University, particularly the Faculty of Medicine, whose members did so much to assist in maintaining the efficiency of the health department of the city both directly and indirectly. He did not agree with those pessimists who said that because the young student of to-day appeared to be frivolous the life of the university was doomed, and he quoted in support of this the following statement, made 60 years ago by Acland with reference to Oxford University: "the Government, trade, laws, are not only being criticised and changed, but the conditions of modern society stimulate nervous excitement, and the late hours and feverish life are undermining our very existence." He was reminded by this of the famous saying about another institution that the more it changed the more it remained the same.

On rising to reply Prof. Hall was greeted with prolonged applause. He spoke of the dinner held a hundred years before at the Tontine Hotel, the only record of which was that Dr. Knight was in the chair and that after dinner "several appropriate speeches were made and the convivialities were kept up till a late hour." To-day, said Dr. Hall, they were met to celebrate not a single stone, but a completed building, not at a small inn where post-horses might be changed, but at a large railway terminus hotel; but in spite of these changes there were the same guests at the two functions, including the Master Cutler, town collector, and the chairman of the infirmary. Prof. Hall was glad to say that one of the earlier teachers of the school, Dr. F. Woolhouse, was still alive, though living in retirement in Sheffield, whilst a student of the first 50 years, Dr. A. Payne, still practised in the city, and had been at the Congregation that morning. The school had been saved in its youth, he thought, by two things, a man and an event, the man being Arthur Jackson and the event the founding of Firth College, to which it subsequently became affiliated. Prof. Hall went on to speak of some of the work done by those who had been teachers there, notably Dr. Christopher Addison, Prof. Arthur Jackson, and Sir John Robertson, who, whilst working in inadequate temporary premises as a pathological laboratory, persuaded the Government to institute the compulsory notification of pulmonary tuberculosis. Finally he referred to a generous gift by Dr. Walter Smith Kay, who has presented a sum of money to the Faculty to provide a yearly gold medal to be given to that student who shall have shown most efficiency in the study of mental diseases, a gift which was very happy, because that Sheffield has just instituted a scheme of out-patient mental clinics at the two large voluntary hospitals in association with the South Yorkshire Mental Hospital.—There were a number of other toasts and replies before the luncheon ended.

Reception at the University.

In the evening a reception and conversazione was held at the University, at which the various faculties had arranged a series of demonstrations and exhibitions. The guests were received in the Firth Hall by Colonel and Mrs. H. K. Stephenson and Sir Henry Hadow, after which they were invited to view the various experiments being conducted in all the University departments. In the Firth Hall itself were exhibited a large number of engravings and paintings of famous medical men of the last 100 years, together with old medical text-books and diplomas. The librarian had also displayed in the Edgar Allen Library the valuable collection of ancient books and manuscripts.

That the whole of the centenary celebrations were a success was due in no small measure to the work of the committees and members of faculties who helped to organise it, as well as to the proverbial fine weather which attends anything of importance to the City of Sheffield.

THE OSLER CLUB.

THE Osler Club was founded recently in Sir William Osler's memory by a group of medical students, as an overt acknowledgment of the inspiration of his writings. The general object of the club is for the study of the history of medicine, and it is intended that a general meeting shall always be held on Osler's birthday. Accordingly, on the evening of July 12th, the club met and entertained a number of guests at a meeting held at Wimpole-street, at the house of Mr. Philip Franklin, whose son, Mr. A. Franklin, is the honorary Secretary of the Club.

Sir Wilmot Herringham addressed the meeting in informal speech, the description of which as an Oslerian Oration he deprecated. He spoke of Osler's love of rare cases, not because they represented extremes of normal physiology, but because their rarity appealed to him as an artist. He told how the young Osler, inspired by the German educational "system," and by what he had seen of practical training in Great Britain, completely altered the outlook of medical teaching in America, and how later he was the prominent advocate for the establishment of clinical units in this country. Dwelling happily on Osler's personal charm and affectionate nature, Sir Wilmot closed a speech of genuine feeling.

Dr. E. O. Meynen, representing the German Ambassador, proposed a vote of thanks to the Orator, and wished particular success to the club as an agency for the promotion of international goodwill, under a patron saint whose name was held in reverent esteem in Germany.

Sir Humphry Rolleston then spoke of "Osler as a Human Being," showing that it was the combination of so many different personalities in one body that made Osler the beloved man that he was. Others present who joined in an Osler symposium were Prof. D. Fraser-Harris, who spoke of him as a physiologist; Dr. H. H. Scott, who dwelt on his merits as a naturalist and comparative pathologist; Dr. Andrew Balfour, who testified to his deep interest in tropical medicine; Sir Squire Sprigge, who regarded him as a great man of letters, Sir Walter Fletcher, Dr. Franklin Martin (President-Elect of the American College of Surgeons), Dr. J. D. Rolleston, and Dr. Ernest Jones.

Among other guests of the club were Sir Thomas Lewis, Dr. Burton Haseltine (Chicago), Mr. Geoffrey Keynes, Mr. S. Damian, Dr. Henry Viets (Boston), and Mr. Philip Franklin, and an opportunity was given to see an exhibition of a selection of Osler's writings, literary and scientific, of biographical appreciations and of books inspired by him, bearing witness to the many-sided nature of his interests and enthusiasms.

A reproduction of the Sargent crayon sketch of Sir William Osler, lent by the Royal Society of Medicine, occupied the place of honour, and through the kindness of several London librarians, pictures of the Triumvirate of British Medicine—Linacre, Harvey, and Sydenham—were displayed, together with some of Osler's favourite books—Religio Medici. The Anatomy of Melancholy, Lettres de Gui Patin.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Congress of the Royal Institute of Public Health.

THE plans for the Congress of the Royal Institute of Public Health, which is to be held in Dublin from August 15th to 20th, are approaching completion. The honorary President of the Congress is Mr. James McNeill, Governor-General of the Irish Free State, and the President is Mr. Richard Mulcahy, Minister for Local Government and Public Health. The work of the Congress will be carried out in four sections: Section I., State Medicine; Section II., Bacteriology, Pathology, and Biochemistry; Section III., Maternity and Child Welfare, School Medical Inspection; Section IV., Production and Control of Milk and Food. Several interesting discussions have been arranged, and a pleasant programme is also prepared for the entertainment of members of the Congress. It is an additional attraction that the National Athletic Festival of Ireland, the Failteann Games, is to be held in Dublin at the same time.

The Dentists Bill.

The Bill for the registration of dentists in the Irish Free State has at length passed the Senate. There was no difference of opinion on the general principles of the Bill, which follows closely the British Act of 1921, but a great deal of time was spent in consideration of the position of unqualified dentists who had failed to register under the Act of 1921. Many senators appeared, indeed, to be more interested in the protection of unqualified dentists than in the protection of the public. Finally, the Minister in charge of the Bill accepted an amendment, by virtue of which unqualified dentists who have been practising dentistry as their principal means of livelihood since 1921, and were then 21 years of age, will be permitted to register as dentists if they succeed in passing an examination conducted by the Minister or by the Dental Board. It is somewhat of an anomaly that the Dental Board is mentioned, since all other matters concerning the education of dentists are put under the supervision of the Medical Registration Council, and not of the Dental Board.

The Local Authorities Bill.

Mr. De Valera's Bill to amend the Local Authorities Act of 1926 was defeated last week in the Dail on the motion for its second reading. The Government is to be congratulated on its determined opposition to the Bill, which would have gone far to nullify the good effects of the principal Act. It is doubtful, indeed, whether Mr. De Valera's party was very anxious that the Bill should pass, and the genesis of the Bill probably lay in the desire to court popularity with the members of the local authorities who have been "disquieted" by their loss of power and patronage. In the lengthy debates of the past few weeks no single case was quoted in which the present method of making local appointments could fairly be said to be at fault. In regard to medical appointments there cannot be any doubt that the electors have under the present system a much wider range of choice than electors had formerly. Before the Act of 1926 only a few candidates, possessed of local influence, presented themselves as candidates for an appointment. Now that appointments are made on their merits by an independent body the choice lies not among three or four candidates, but among three or four score.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 7TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 182 (last week 219); scarlet fever, 1715; diphtheria, 912; enteric fever, 52; pneumonia, 716; puerperal fever, 45; puerperal pyrexia, 85; cerebro-spinal fever, 14; acute poliomyelitis, 13; acute polioencephalitis, 2; encephalitis lethargica, 31; continued fever, 1; dysentery, 13; ophthalmia neonatorum, 106. No case of cholera, plague, or typhus fever was notified during the week.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on July 10th–11th was as follows:—Small-pox, 41 under treatment; scarlet fever, 1757; diphtheria, 1889; enteric fever, 16; measles, 448; whooping-cough, 176; puerperal fever, 31 (plus 6 babies); encephalitis lethargica, 66; poliomyelitis, 1; "other diseases," 30. At St. Margaret's Hospital there were 21 babies (plus 16 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox or enteric fever, 33 (7) from measles, 4 (0) from scarlet fever, 21 (4) from whooping-cough, 22 (5) from diphtheria, 51 (7) from diarrhœa and enteritis under two years, and 24 (3) from influenza. The figures in parentheses are those for London itself.

Of the 26 fatal cases of measles outside London 8 were reported from Liverpool and 4 from Newcastle-on-Tyne. Of the 17 cases of whooping-cough outside London 4 were reported from Birmingham. During the same week Glasgow reported 7 deaths from whooping-cough. Liverpool and Salford each reported 3 deaths from diarrhœa.

The number of stillbirths registered during the week was 308 in the great towns (corresponding to a rate of 41 per 1000 births), including 54 in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are notified:—Surg.-Capt.: C. T. Baxter to *Vivid* for R.N. Barracks, Devonport. Surg.-Comdrs.: T. J. O'Riordan, lent to N.Z. Division; L. Warren to *Queen Elizabeth*; A. Craig to *Pembroke*, for R.N. Barracks, Chatham, and to *Emerald* (on recommg.); J. D. Keir to *Pembroke*, for R.N. Barracks, Chatham; and A. G. Taylor, to *Cairo* (undated). Surg. Lieut.-Comdrs: J. W. Tighe to *Pembroke*, for Sheerness Dockyard; H. L. Douglas to *Cairo*; and J. E. Clark to *Tamar*. Surg. Lieut.: E. J. Weeks to *Fisgard*. Surg. Lieut. (D.): G. Baker to *Victory*, for R.M. Infirmary, Portsmouth, and to *Victory* for R.N. Barracks.

ROYAL ARMY MEDICAL CORPS.

Maj. W. J. Dunn retires on retd. pay and is granted the rank of Lt.-Col.

The undermentioned Capts. to be Majs.: J. Cullenan, C. O. J. Young (Prov.), and R. N. Phease.

Temp. Lt. P. Weiner relinquishes his commn.

TERRITORIAL ARMY.

J. H. Dunn (late Surg. Sub-Lt. R.N.V.R.), H. Broadbent, F. H. Hollingshead, Lt. R. I. Poston, 2nd Lt. S. G. M. Lynch, and F. Lawrence to be Lts.

ROYAL AIR FORCE.

Flying Officer F. A. O'Connor resigns his short service commission.

INDIAN MEDICAL SERVICE.

Lt.-Col. G. O. F. Sealy retires.

S. Hartley to be Capt. (on prob.).

Bijeta Chaudhuri, Shankar Sahai Bhatnagar, C. F. J. Cropper, K. H. A. Gross, E. V. Claydon, V. H. Sarland, J. Acheson, E. A. O'Connor, J. P. J. Little, P. L. O'Neill, and V. T. J. Lynch to be Lts. (on prob.).

THE NEW BETHLEM HOSPITAL.—Last week Prince Arthur of Connaught, in place of the Duke of Connaught, his father, who has been indisposed, laid the foundation-stone of the new Bethlem Hospital at Monk's Orchard, Shirley, near Croydon. The Lord Mayor of London recently presided at a dinner at the Mansion House in aid of the building fund. The cost of the new buildings will be £450,000, of which £330,000 was available. Towards the balance of £120,000 £42,000 has already been raised; of this sum Sir Charles Wakefield, President of the Royal Hospitals of Bridewell and Bethlem, has given £25,000.

Obituary.

WILLIAM DYSON, M.D. LOND., J.P.

THE death, at Sheffield, on July 9th of Dr. William Dyson in his seventy-ninth year will recall to many members of the medical profession in the Northern Midlands a name which was familiar to them in the later decades of last century and the first half of this.

Born in 1849 at Thurgoland, near Penistone, of an old Wesleyan stock, and educated at the then Wesley College, Sheffield, Dyson's medical studies were carried out at University College Medical School, London, where he was a fellow student with, and a close friend of, Sir Thomas Barlow. At his final M.B. Lond. in 1873, he took honours in medicine and midwifery, afterwards holding resident appointments at University College Hospital. He then returned to practice in Sheffield, being appointed physician to the Sheffield Public Hospital (now the Royal Hospital) in 1876, and resigning this post in 1885 on being elected physician to the General (now Royal) Infirmary, with which institution he remained in active connexion for 27 years. On his retirement in 1912 he was made a consulting physician. During this time his success as a consultant was very great. It began early, continued long, and extended over a wide area. He came to Sheffield just when medical knowledge was undergoing great developments, and as a representative of the new school he soon displaced such few older competitors as there were. For the next 25 years he had the field of medical consulting work almost entirely to himself. It was, writes one of his colleagues, his gentleness and sympathy in dealing with all with whom he came in contact, coupled with an exceptionally thorough knowledge of his professional work, which no doubt gave the key to his wide popularity as a consultant and to his very successful practice.

Dyson took an active interest in the school of medicine, of which he was a member of the teaching staff for many years. When the University College was founded in 1897 he became the first professor of medicine, and on retiring from that post in 1901 was appointed emeritus. On the death of William Favell in 1897 Dyson was appointed a Vice-President of the College in his place, and became the recognised leader of the profession. In the same year he was elected to a vacancy on the Town Trust, of which he remained an honoured member until his death. He was also, as his father before him, on the Commission of the Peace for the West Riding. He took an active interest in the Sheffield Medico-Chirurgical Society the Yorkshire branch of the British Medical Association, and the West Riding Medical Charitable Society, holding office in each. When the British Medical Association proposed to hold its annual meeting in Sheffield in 1908, Dyson was invited unanimously by his colleagues to be nominated as its President. This, however, he was obliged to decline on the grounds of health.

Of a modest and retiring disposition, Dyson was seen at his best in the medical wards which he loved. Successive generations of practitioners and students all testify to his unusual abilities as a clinician and as a teacher. Public work and ceremonial occasions were distasteful to him, and he found the effort of them very great. Always somewhat delicate, writes the same colleague, the strain of his large practice told heavily upon him. Nor is this a matter for surprise. The motor-car had not then come into use. All country work had to be done by train or by carriage, so that a large consulting practice in those days involved very long hours indeed, and much weary time spent in travelling. To those outside the area in which his practice lay, Dyson's name was less well known than his clinical knowledge and skill deserved. The constant calls of practice allowed him little time for writing after a few early contributions to medical literature on cases of special interest. By colleagues and students he was beloved as an intimate friend.

Dr. Dyson retired from practice some years ago. In 1916 the loss of his younger son, William Hubert, an officer in the Queen's Westminster Rifles, who died of wounds in the German lines after leading a raid into the enemy trench, was a blow from which he never recovered. His death occurred only a few days before the centenary of the Medical School, and a fitting tribute to his great services was paid by the Chancellor before the opening of the Degree Congregation at Sheffield University in connexion with its celebration. His widow, a son—Dr. Ernest Andrews Dyson, of Guildford—and a daughter survive him.

Correspondence.

"Audi alteram partem."

INTENSIVE SERUM TREATMENT OF SEVERE DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—We should like to add our testimony to that of Dr. H. S. Banks and Dr. G. McCracken as to the value of *very* large doses of antitoxin in the treatment of the severe toxic case of diphtheria. In this hospital we have been accustomed, for several years past, to employ doses of "concentrated" antitoxin comparable in unitage with those used by Dr. Banks and his colleague. There has hitherto been one important difference between our procedure and theirs—viz., the route of injection. The subcutaneous route is never employed by us; the vast majority of our cases has received antitoxin intramuscularly. In only a minority of the worst class of case a relatively small intravenous injection has been given in addition. Until we were made aware, some few weeks ago, of Dr. Banks's work we had been fairly satisfied with our recovery-rate; but the record of his results has led us to analyse in detail the cases admitted to Little Bromwich Hospital with a diagnosis of diphtheria during the 12 months of 1927, with a view to finding out whether our recovery-rate might be still further improved.

As regards case mortality over the whole series, consideration of the figures which we submit below will, we think, show that there is little to choose between Banks's and McCracken's percentage and ours. But detailed consideration of the case mortality and complication-rate in the different classes of case shows that the employment of large doses of antitoxin by the intravenous route produces results far superior to those obtained, in comparable cases with comparable unitage, when the intramuscular route is employed. During the 12 months ended Dec. 31st, 1927, a gross total of 1842 cases was admitted to this hospital with a diagnosis of diphtheria. From this total has to be subtracted no less than 542 cases which were examples either of so-called "bacteriological diphtheria" or conditions other than diphtheria. This leaves a net total of 1302 cases of indubitable clinical diphtheria. These 1302 cases are analysed in the table.

Comparing Dr. Banks's Classes A and B which received, almost exclusively, large doses of antitoxin intravenously, with our similar classes, it will be seen that his case mortality is 10 per cent. *less than* ours in Class A and non-existent in Class B (against our 4·6 per cent.); and whereas Dr. Banks dwells upon the rarity of, at any rate, severe pareses, such complications, in our Class A occurred in *more* than a third of the survivors. In the remaining groups our paresis-rate (all types being included) is satisfactorily low. Of the 19 cases in our Class A who received a small dose of antitoxin intravenously in addition to a large dose intramuscularly, 7 were hopelessly toxic and died within a few hours of admission; 2 others died within 15 days of myocardial failure, and 1 in the fifth week of diaphragmatic paralysis. Of the survivors 6 recovered without complications; the remaining 3 had palatal paresis only.

This year we have largely increased our intravenous dosage in the Class A case. We now give 40,000 or more units by that route in addition to a following-dose intramuscularly. The results in a consecutive series of 19 cases are as follows: 1 died within a few hours of admission; 3 died later from myocardial degeneration. Of the remainder 14 have recovered with nothing more serious than slight palatal paresis and one after palatal and pharyngeal paresis of greater severity. Until it comes about that a preventible disease is prevented, it is some satisfaction to know that the large dose of antitoxin given intravenously is capable of obviating at least some of the tragedies which otherwise must occur.

Analysis of 1302 Cases of Indubitable Clinical Diphtheria.

A = Malignant or severely toxic. B = Moderately toxic. Ci = Moderate. Cii = Mild. D = Laryngeal (purely).

	A.	B.	Ci.	Cii.	D.	Total.
Cases	142	87	76	975	22	1302
% cases in each group	10·9	6·6	5·8	74·8	1·6	
Aver. no. of units of antitoxin ..	I.M. 80,000†	I.M. 50,000	I.M. 32,000	I.M. 8,000–24,000	I.M. 8,000–24,000	
Deaths ..	46	4	1	1	4‡	56
Of these died under 48 hrs.	22	2	—	—	—	
Gross case mortality %	32·4	4·6	1·3	0·1	18	4·3
Case mortality minus 48 hr. deaths	17	2·3	1·3	0·1	18	2·46
Recovery *without* pareses* ..	46 (32·4 %)	66 (75·8 %)	71 (93·4 %)	959 (98·3 %)	18 (100 %)	1,160 (89 %)
Recovery following pareses* ..	50 (35·2 %)	17 (19·6 %)	4 (5·3 %)	15 (1·6 %)	—	86 (6·7 %)

* Percentages calculated on survivors. † Plus I.V. 12,000 in 19 cases. ‡ All broncho-pneumonia.

We should like to congratulate Dr. Banks and Dr. McCracken upon their results.

We are, Sir, yours faithfully,
E. H. R. HARRIES.
W. M. MACFARLANE.

City Hospital, Little Bromwich, Birmingham,
July 11th, 1928.

RADIOTHERAPY OF CANCER.

To the Editor of THE LANCET.

SIR,—In your issue of July 7th (p. 34) there is a short description of the findings of the subcommission of experts charged by the Cancer Commission of the League of Nations with the study of radiotherapy of cancer, at its preliminary meetings on June 18th and 19th, under the presidency of Prof. Cl. Regaud. One paragraph reads:—

> "On the broader questions relating to the treatment of uterine cancer by radiology the President submitted a series of considerations which, after a general discussion, were adopted by the subcommission as representing the most important directions to which its future discussions should be directed, and on which definite recommendations should be made in due course to the Health Committee with a view to publication. Among these considerations were: 1. Propaganda among doctors and the general public in order to ensure the early discovery and early and correct treatment of cancer of the uterus. 2. Increase in the number of consultation centres. 3. Organisation of centres for microscopic analysis in order to ensure early diagnoses. 4. Recommendations for the organisation of the correct treatment of the disease. 5. Recommendations for the radio-therapeutical equipment of clinics. 6. Disadvantages of out-patient treatment. 7. Recommendations for the compilation of reliable statistics. 8. Recommendations for special scientific research."

I should like, with your permission, to draw attention to the fact that on May 14th last I sent you a contribution on radium therapy in which almost identical suggestions were embodied. These suggestions of mine were:—

1. Large hospitals with many cases of sufferers from carcinoma or sarcoma should engage in research and treatment by radium and radio-active substances.

2. Owing to scarcity and the danger of supply being at least temporarily exhausted, or the market price altered by increased demand, small hospitals, where the radium would lie idle for periods, should not be encouraged, and suitable cases should be referred to large centres. If needs be, the patients' fares and maintenance might be paid; as in Sweden. A small quantity of expensive radium in any case is useless, and cannot be applied without expert technical guidance.

3. These large radium centres would link up throughout the country and deal with the cancer plague territorially—each to be a centre for treatment, research, and teaching, with post-graduate and student courses—not only in radium therapy, but also as anticancer centres for investigations from every aspect of the whole problem, with sociological, pathological, biological, medical, surgical and radio-therapeutic measures, all being carried on by team methods.

4. Frequent opportunities should be made for free intercourse and discussion on new methods between all anticancer centres, with opportunities to see the best work of other countries, with interchange, as necessary, of working members of the staffs.

5. Statistics of results, with exact technique, to be kept, compared, and published for the benefit of other investigators.

6. No effort should be spared to obtain the attendance of patients when in an early stage. With the fear of operation reduced, this should soon be an easy matter, subject to proper enlightenment and encouragement of the public through the publicity of the Ministry of Health, the public health authorities, and the private practitioner, whose coöperation is most essential to allay the dread of sufferers who shrink from the idea of the operating table, and to hearten them to seek treatment voluntarily at the earliest moment by the newest scientific methods, painlessly applied.

My great interest in this matter has been stimulated from the reason that, although I have been brought up for the greater part of my life in surgical operating theatres, within the last few months I have been so strikingly impressed by recent results of radium treatment that I feel most strongly on the question.

I am, Sir, yours faithfully,
SPENCER MORT.

North Middlesex Hospital, Upper Edmonton,
July 10th, 1928.

MIGRAINE.

To the Editor of THE LANCET.

SIR,—Dr. Purdon Martin, writing in your issue of July 14th (p. 82), is, I think, under a misapprehension as to my point of view. He says that I have regarded migraine as a psychoneurosis. What I have said is that "however skilful the ophthalmic surgeon, and however meticulous the general treatment, although relief from the actual paroxysms may be obtained, *the patient does not become well*, unless the psychological situation is elucidated and adjusted." This statement, empirical though it may be, is, I believe, true; and I do not know many people who will care to contradict it. I do not know if Dr. Purdon Martin was amongst the audience who, last night, listened to an admirable address by Dr. Seif, of Munich, before some of the Adlerian groups in London, but he could hardly have heard a more convincing statement of the reasons for treating, not hypothetical and hypostatised diseases, but *individual patients* whose life and health is disordered. And the fact is that, when the psychological state, as well as the physical errors, of the migrainous is adjusted, the patients get well and keep well. Whether or no this fact implies that "migraine is a psychoneurosis" I do not know, in the absence of a definition of a psychoneurosis. Nor do I know why the suggestion that migraine is a psychoneurosis should seem inadequate to account for such a symptom as ophthalmoplegia. I do not find it more difficult to believe that paroxysmal ophthalmoplegia should disappear when psychical states are adjusted than I do to believe that diarrhœa, involuntary lacrymation, involuntary micturition, impotentia coeundi, angina pectoris, "functional" paralysis, hystero-epilepsy, and a hundred other conditions should occur when psychical states are disturbed and disappear when they are adjusted.

I do know this, that some years ago I had ophthalmoplegic migraine of so persistent a nature that several kind and skilful friends begged to be allowed to do something to one of my tendons! I am grateful to them, but much more grateful, on the one hand, to those who insisted on correction of the "organ inferiority"—irregular astigmatism and muscular defect—by glasses, and on the other, to those who helped me to see the psychological error and difficulty. But my position is diametrically opposed to that of those who, regarding "migraine as a psychoneurosis," let it go at that, and (in another direction) to that of those who, while believing migrainous attacks arise "in some way from a functional disorder of the vegetative nervous system," do not inquire what are the psychological difficulties correlated with this disorder. The proof of the pudding is in the eating. Migrainous people, unless they are old, and their attacks have become organised, and their arteries stiff, and their kidneys inadequate, *do get well;* if, that is, in addition to correction of their organ-inferiorities and adjustment of their physiological divagations, investigation and adjustment of their psychological troubles is carried our. Explanations and theories have a secondary place. The thing *works*.

I am, Sir, yours faithfully,

Wimpole-street, W, July 13th,. F. G. CROOKSHANK.

To the Editor of THE LANCET.

SIR,—Dr. Martin's article gives a very comprehensive view of this malady and its suggested treatment from the physical side. Scant attention, however, has been given to migraine as a psychoneurosis. In my experience the migrainous sufferers are usually "thinkers." Much phantasy formation is their pleasure-ground. Their psychical energy remains dammed up rather than expressed in action. The migraine sufferer is usually the prey of his repressed anger, rage, and humiliation, which he turns in towards himself. Migraine ensues when an uncongenial task is to be performed. It is a means of being in the limelight when other means fail. The greatest relief lies in helping the patient to see himself and to make him conscious of his fraudulent trick, which is a means of heightening his own ego-consciousness and his desire for superiority. The energy, when liberated, must be directed into fresh channels of expression. Readjustment is necessary. General measures do help the migraine sufferer, but they do not *cure*. The psychological situation must be cleared up. Dr. F. G. Crookshank, in his little book, gives most valuable information on this tiresome malady.

I am, Sir, yours faithfully,

Harley-street, W., July 14th, 1928. ESTELLE COLE.

DIPHTHERIA CARRIERS.

To the Editor of THE LANCET.

SIR,—Dr. Harvey, in his interesting article in to-day's issue upon the treatment of diphtheria carriers, does not mention the possibility of the bacillus being carried in a tooth cavity. Some thirty odd years ago I saw a boy of between 10 and 12 from Dover. He and his sister had both carried diphtheria. Both had their tonsils and adenoids removed, and the bacilli disappeared from the girl's nose and throat completely, but continued in the boy's throat. I could find nothing abnormal to account for his continuing a carrier, the tonsils and adenoids having been most effectively removed. It occurred to me, however, to search his teeth with a mirror, and I thus discovered a cavity in the posterior face of his left last lower molar, which was completely hidden from ordinary inspection. I suggested searching this cavity, and, if the bacilli were found there, the appropriate treatment of the tooth. My advice was acted upon, the swab gave ample evidence of a nest of diphtheria bacilli, the cavity was cleaned out and filled, and the bacilli disappeared from the mouth within the week, after the boy had been a carrier for six months.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY.

Wimpole-street, W., July 14th, 1928.

ANATOMICAL NOMENCLATURE.

To the Editor of THE LANCET.

SIR,—In your annotation of May 26th under this heading you do me, I believe, an injustice, but that is a detail. The Anatomical Society, at its recent meeting in Manchester, appointed a committee with a view to revision of the Basle Nomenclature (B.N.A.). I beg now through you to offer my services, unofficial, unconditional, whole-hearted, and loyal, in the way of criticism and suggestion *only*, hoping to be able to indicate how, beginning with the B.N.A. and applying the principles advocated by its own authors, we may evolve such a nomenclature as will win favour and survive solely because of its fitness. In the past I have made many mistakes. I take what comfort I can from the thought that he who makes no mistakes may make nothing else.

I am, Sir, yours faithfully,

Leeds, July 11th, 1928. WM. CUTHBERT MORTON.

NOTES ON CURRENT TOPICS.

Reorganisation of Offices (Scotland) Bill.

IN the House of Lords on July 16th the Reorganisation of Offices (Scotland) Bill was read the second time.

HOUSE OF LORDS.

THURSDAY, JULY 12TH.

Child Destruction Bill.

ON the motion of Lord DARLING the report of amendments to the Child Destruction Bill (formerly the Infanticide Bill) was received and further amendments, mostly of a drafting nature, were agreed to.

On July 16th the Child Destruction Bill was read the third time, and passed.

MONDAY, JULY 16TH.

DOGS ACT (AMENDMENT) BILL.

Lord Banbury's Amendment.

On the motion for the third reading of the Dogs Act (Amendment) Bill, which has already passed the Commons.

Lord BANBURY moved to leave out Clause 2. He said that under the Act of 1906 Clauses 3 and 4 must be read together. Clause 4 was the clause which under this Bill it was proposed to leave out and substitute for it another clause which he (Lord Banbury) proposed to leave out, thus leaving the law in exactly the same position as it was now. Clause 4 of the Act of 1906 said that:—

> "Any person who takes possession of a stray dog shall forthwith either return the dog to its owner or give notice in writing to the chief officer of police of the district where the dog was found."

Clause 3 which must be read in conjunction with it said:—

> "Where a police officer had reason to believe that any dog found in a highway or place of public resort is a stray dog, he may seize the dog and may detain it until the owner has claimed it and paid all expenses incurred by reason of its detention."

Subsection (5) said:—

> "No dog so seized shall be given or sold for the purposes of vivisection."

That was the law as it stood now. In February of this year a Bill was introduced in the House of Commons, the chief object of which was to make owners of dogs liable for injury to poultry. To that he had no objection. But it then went on to repeal Section 4 of the principal Act which he had just read and to substitute this:—

> "Any person who takes possession of a stray dog shall forthwith either return the dog to its owner or deliver the dog to a

police officer of the police area in which the dog was found and inform that officer where the dog was found."

The clause further said :—

"A dog which has been delivered to a police officer under this section shall be treated as if it had been seized by that officer in pursuance of Section 3 of this Act."

That was to say that if any dog was seized by a police officer it should be treated in pursuance of the Act of 1906, with the result that no stray dog or lost dog which was taken to the police would be used for the purpose of vivisection. That was the Bill as introduced in the House of Commons, as it passed the second reading in the House of Commons, and as it passed the Committee stage in the House of Commons. On the Report stage, however, an amendment was moved to leave out the clause and insert another one which was in the Bill before their lordships. The effect of that clause was that the protection which existed at the present moment against the use for vivisection purposes of a stray or lost dog was done away with. Under the clause which he proposed to leave out there were two alternatives. A person who found a stray dog had to take it to the police station. If the person did not want to keep the dog the police took possession of it, and they could not sell it for the purposes of vivisection. On the other hand, if the person who found the dog was a person whose object it was to look for stray or lost dogs in order to make money out of them by keeping them for a month and then selling them for the purposes of vivisection what was to prevent him? If a person was not very scrupulous and he found a dog with a collar on it he could remove the collar and throw it away before taking the dog to the police station. In that case the identification of the dog was to a certain extent lost and the profit which the man was going to make was pretty sure. Knowing human nature and bearing in mind a case that occurred not very long ago when two dogs were found in a sack, and another case in which a dog had been taken off the doorstep of its owner, and they were all found at an institution where vivisection was carried on, he ventured to say that it was pretty certain that under this alternative of the law there would be people who would take advantage of it for the purposes which he had suggested. He would prefer if their lordships left out Clause 2, that the clause which was originally in the Bill should be reinserted. But he did not wish to insist upon that if their lordships would only leave out Clause 2. He hoped the House would support him because this was an insidious attempt to obtain all stray or lost dogs for the purposes of vivisection.

Lord Dawson on Vivisection.

Lord DAWSON of PENN said that they had to consider two varieties of dogs. One was the owned dog. Was there any Member of that House who would not take any precaution necessary to preserve the owned dog to its owner? Then there was the stray dog, which wandered about eking out such a living as it could, uncared for, a misery to itself and a danger to the community. The extent of that problem was shown by the fact that each year something like 30,000 stray dogs were destroyed in the City of London alone. Was it not obvious, if there was to be the same provision for both varieties of dogs, that the owned dog would suffer? If they put an embargo on the use of the stray dog for experimental purposes, would they not correspondingly endanger the owned dog? The Bill provided extremely well for that contingency. Its provisions would help in the identification of the owned dog and diminish the chances of mishap. Therefore it deserved the support of that House. It was clear that the object of Lord Banbury was not the protection of the owned dog. Underlying all Lord Banbury's remarks was this, that he was making this an opportunity for a flank attack on the use of dogs for experimentation. He (Lord Dawson) would take up his challenge, for it was clear enough that the question of experimentation on animals stood or fell by the use or not of dogs. Whichever way they approached this question of experimentation on dogs, surrounding it by as much misrepresentation of fact as they would—and there was no subject he knew of which was more misrepresented than this—they always arrived at two aspects of the question. The first one was: Do material advantages accrue to mankind from experimentation on dogs and experimentation on animals in general? The second question, a totally different one, was: Whatever those advantages may be, is it ethically justifiable that mankind should take advantage of them?

The first question, whether material advantages accrued to mankind, was surely a question for those people with skilled knowledge. There was no one else who could give the answer "Yes" or "No." Supposing, for example, that they were building a bridge across a river. They might decide the policy as to whether the bridge should be built or not, but whether the bridge should be built of chrome steel or manganese steel, or whatever the distribution of the stresses should be, would be left to the engineers. The problem of the engineer was nothing in comparison with the problems which arose in connexion with the body and mind of man. He would not trouble their lordships with too much on the question whether man did gain advantages from experiment or not, but there was this remarkable fact. We were accustomed to find experts differing materially, but on this question of experimentation on dogs there was such a consensus of opinion among the medical men of the civilised world that it amounted to a practical unanimity. They had recently had a conference representing every aspect of medicine and surgery, and of the sciences on which medicine and surgery rested. A more representative conference there could not be, and that conference said this to the British nation, that without experimentation on animals medicine and surgery could not carry on. He did not mean that they would not carry on; of course they would do their best; but, intellectually, they would come to stagnation. He would put the matter in another way. Supposing he were asked to find a staff for a hospital of, say, 200 beds in London, and had to find surgeons and physicians of sufficient standing on the one hand, and who would embrace the principles that Lord Banbury advocated. He had to tell the House that he could not find such a staff; it did not exist. That would indicate to the House to what extent medical unanimity prevailed.

The Ethical Aspect.

The honest opponents were those who approached the question from the ethical standpoint. He had in mind the man who said: "Whatever the advantages that accrue to mankind, it is ethically unjustifiable that you should make use of them." He respected that man, provided that he did not himself make use of those remedies in his time of trouble. It was a question for the public. They invited the public to answer that question. It was for them to say "Yes" or "No." If they said "Yes," by all means let them have the legislation which would make all these things illegal. That, at any rate, would be an honest and straightforward course. If, on the other hand, the answer was "No; we do not wish to stop these things," then he said: "For Heaven's sake leave us alone to go on with our work and do not harass us day by day and year by year." He had admitted that the question whether it was ethically justifiable to make use of experiments on animals should be decided by the public, and what was true of the dog was true of other animals. The medical profession told the House, with a real sense of responsibility, that they could not do without dogs—that they could not substitute other animals in every case. Their universal rule was that they never used an animal higher in the scale of creation than was absolutely necessary. They used the lowest animal possible, compatible with doing their best and getting successful results. In order that the public might be in a position to answer the question whether it was ethically justifiable, it would be of some profit if he tried to clear away a few misconceptions. He would take the question of pain. Was it likely that those of them whose upbringing had been in associating with pain from their student days were going to do anything which would needlessly increase pain when their whole careers were spent in assuaging it? They were not likely to be less sensitive than Lord Banbury on the question of inflicting pain. On the contrary, they knew more about it and what it meant. Therefore he would not waste time in dwelling upon any question of the indifference of the medical profession to pain. As to the 30,000 animals that were anæsthetised every year, all they asked was that they should be made use of not only for the benefit of mankind, but for themselves. It must be borne in mind that the large majority of experiments on animals were carried out under anæsthetics, and the dogs and other animals were completely ignorant of what was going on. He would go further than that. He would admit that there were a minority of cases where animals were given diseases in order to aid in the diagnosis of disease in man. He admitted, further, that there were, from time to time, what they called survival experiments. He would tell their lordships exactly what survival experiments meant. A greater part of the treatment of gastro-intestinal disease in modern times depended mainly upon experiment on animals. One of the most distinguished men of modern times was Prof. Pavlov, of Russia. As an example, he would take the case of a man who was going to be short-circuited for duodenal ulcer. They might take his pain and distress and divide them into three parts. There was, first, the stage of anticipation. There was that stage when he had to make up his mind to face the risks to himself and his family, and when he said to himself, "Supposing I do not survive. What is going to happen to me in my profession?" All these agonies of mind far exceeded distress of body. Man had to go through all that, not the animals. The animal had none of that, and he had no power of anticipation whatever. The second stage was that of the actual operation of short-pectoris, "functional" paralysis, hystero-epilepsy, and a hundred other conditions should occur when psychical states are disturbed and disappear when they are adjusted.

I do know this, that some years ago I had ophthalmoplegic migraine of so persistent a nature that several kind and skilful friends begged to be allowed to do something to one of my tendons! I am grateful to them, but much more grateful, on the one hand, to those who insisted on correction of the "organ inferiority"—irregular astigmatism and muscular defect—by glasses, and on the other, to those who helped me to see the psychological error and difficulty. Ex-Service Men and Medical Treatment.

Mr. STEPHEN asked the Minister of Pensions what remedy an ex-Service man had when he was recommended by the Ministry for treatment at home by his panel doctor and the panel doctor certified that treatment by the Ministry was necessary.—Major TRYON replied: Where it had been decided that a case was either not eligible for or did not require such a course of treatment as is provided by the Ministry of Pensions the case would fall to be dealt with under the ordinary arrangements available to insured persons under the National Health Insurance Acts.

Mr. STEPHEN: If the Minister decides that treatment is not possible and the man's panel doctor considers that
atment by the Ministry is necessary what step has the
then to take?

lajor TRYON: It is quite clear that the Ministry cannot
pt the doctrine that a panel doctor can decide for them.
he man has a grievance against the panel doctor the
nal course would be for him to make an application to
insurance committee.

STEPHEN: But supposing the man has no grievance
st his panel doctor; supposing that he considers that
lvice of his panel doctor is right, is there not a medical
e whose opinion the Ministry and the panel doctor
asked to accept? If there is not, will the Minister
such a referee?

r TRYON: No, Sir. The ordinary course must be
l. The case would be considered by the doctors of
istry of Pensions whose opinions must necessarily
e action to be taken by the Ministry.

: Does the Minister say that the doctors of
y must be the final arbiters in spite of the fact that equally eminent or more eminent medical men may say that the man ought to have treatment?

Major TRYON: No, Sir. The point is that the Ministry of Pensions must decide its own policy and not the panel doctor.

Mr. HARRIS: When doctors disagree would it not be
ossible to have an independent opinion from a specialist,
se it is notorious that doctors often differ on medical

answer was given.

fication in a Case of Lead Poisoning.

NCE asked the Secretary of State for the
ment if his attention had been drawn to the
nald Aubrey Wild, who contracted lead poisoning
rking for Messrs. Locke, Lancaster, and W. W.
Johnson and Sons, Limited, of Millwall; whether
s aware that on application to the certifying surgeon
a certificate the same was refused, the certifying surgeon
eing the same doctor that was in the service of the employers; that the medical referee for the district, who formerly was the employer's doctor, had given a decision that the man was suffering from lead poisoning, but that he was not disabled; and whether, seeing that Mr. Wild was an in-patient in the London Hospital, suffering from lead poisoning, from April 20th until May 14th, after receiving a week's notice on April 15th, he would arrange for the man to be examined by a medical referee attached to another district as, until he was certified, no claim could be made for compensation.—Sir WILLIAM JOYNSON-HICKS replied: The decision of the medical referee under the Act is final, and I have no power to intervene in the manner suggested. I am, moreover, satisfied on inquiry that this case has been most carefully and conscientiously dealt with both by the certifying surgeon and by the medical referee, and I strongly deprecate the implication that these gentlemen, both of whom are medical practitioners of high standing, may have been influenced in carrying out their statutory duties by their connexion with these works. The certifying surgeon is responsible in his official capacity for the periodic examination of workers employed in lead processes under the Lead Compounds Regulations; he also, I understand, periodically examines the other workers and examines workmen newly employed, but has no other interest in the firm. The medical referee used to carry out some three years ago the periodic examinations required by the regulations, but he did this under special appointment from the Chief Inspector of Factories. and he was not, I am informed, otherwise engaged by the firm.

Miss LAWRENCE: In view of the fact that the medical referee for the district did not confirm the decision of the certifying surgeon, and that the certifying surgeon is employed in the manner detailed in the question, does not the right hon. gentleman think that some further inquiries should be made?

Sir W. JOYNSON-HICKS: I have made a very careful inquiry into the position of both these medical gentlemen and their connexion with the firm is very slight, and really, as far as the actual certificate of the medical referee is concerned under the Act that is final, and I have no power to intervene.

Mr. T. WILLIAMS: Is the right hon. gentleman aware that injured workmen practically all over the country have little or no confidence in certifying surgeons who are receiving large fees from employers and then acting for those same employers?

Sir W. JOYNSON-HICKS: In this case the suggestion cannot possibly be made. There is no question of a large fee being received from employers. As far as the general statement made by the hon. Member is concerned, I must really ask him to let me have at least a few of the details of these cases and then I will go into the matter at once, as he has made a very serious charge.

Miss LAWRENCE: I want to ask the right hon. gentlemen whether he has considered the conflicting medical opinions in this case and whether, in view of the conflict of medical evidence, it is not possible to arrange for another examination. The first doctor said that the man had lead poisoning, the second doctor said that he had lead poisoning, but was not disabled, and the third doctor, an independent doctor at the hospital, certified him as actually sound. In view of that conflict of medical opinion cannot the right hon. gentleman have another examination?

Sir W. JOYNSON-HICKS: I will get into communication with the third doctor who the hon. lady says is independent, and ask him to let me have a report on the case. (Cheers.)

Removal of Manchester Tuberculosis Clinic.

Sir THOMAS WATTS asked the Minister of Health if his attention had been called to the objections raised by the residents in the Oxford-road district of Manchester to the proposed removal of the tuberculosis clinic from Hardman-street to that district, and what action he intended to circuiting. There the man and the animal were on a par. They were both under anæsthesia and both felt nothing. The third stage, in some respects the most distressing of all, was that terrible process of building up the man's health after illness, the time of shock, of convalescence. Let them contrast man and animal there. The man might be weeks and months before he was well. In the case of the animal, what happened? They might have an operation on a dog for short-circuiting and the same day it would be playing about with its owner. In the case of an experiment on a monkey, he had himself seen the animal, within 24 hours, sitting on his perch eating a banana. That horrible process of getting well, of recovering from shock, was entirely unknown to the animal. The fact was that it was a slavery of terms. If they read in the papers that one of their lordships had been vivisected and that his appendix had been removed, they would be distressed and horrified; but if they read that he had been operated upon, they would think nothing of it. There was no difference between the one and the other. What had happened to the animal had happened to the man, but what happened to the man was infinitely greater, tenfold or a hundredfold greater, than what happened to the animal. It was necessary to understand what the implication would be if a measure for suppressing experimentation on animals were passed. It would affect the whole range of medicine—the diseases of the gastro-intestinal tract, typhoid, lockjaw—he could go on with a list which would occupy too much of their attention on an afternoon like that. Much of what we knew about gall-stones, dogs had told us. Take jaundice, including the malignant jaundice of dogs. Whereas at one time a dog stricken with malignant jaundice nearly always died, since the discovery of trypan blue the majority of dogs stricken with this disease were saved. In the investigation of disease that animal had to be used which the particular problem required. For instance for the investigation of infantile paralysis, the monkey was the only animal which it was of use to employ. Again, take the case of tetanus. He would not wish that anybody should repeat the war-time experience what that terrible disease was.

Inconsistency of Antivivisectors.

It was important for people to know the consequences of removing from medicine all these results based on experimentation on animals. They had only got to be understood by the public, and then he had no doubt what the public would say. This result would have happened long ago but for the fact that the propagandists against vivisection were not themselves subject to their own gospel. If a propagandist against vivisection was stricken with any of those diseases, he gave an implicit, if not an explicit, consent to vivisection. If those who were against all experimentation on animals were, in their own persons or in their own families afflicted with disease, did their lordships for one moment suppose that they did not adopt the remedies which were based on experimentation? He could assure them that with few exceptions they did adopt them; and was it to be wondered at? Imagine the crisis of love and life in the balance, the crisis of anxious illness. At such a time the theories of the comfortable armchair gave place to more commonsense and reasonable ideas.

He would not be hard on their inconsistencies. Life would be a drab and dreary business if we were always consistent. If the uses of new drugs could not be worked out on animals, the alternative was to work them out on human beings. Perhaps Lord Banbury would form a band of people of conscientious convictions who would allow the medical profession to work out new drugs on them! When it came to working out new drugs like *pituitrin*, *adrenalin*, and digitalin, the question was whether it was better to work them out on animals before they transferred their [illegible] to human beings. He would not say anything against inconsistency if in the hour of trouble the philosophy of antivivisection broke down. He would think humanly of that, but what surpassed the limits of tolerance was that these people could get these remedies when they liked, and yet they were constantly disturbing the minds of unknowing and innocent people in our hospitals.

Hospital Difficulties.

All hospitals in this country were up against the difficulty of getting funds at the present time. They made an appeal in their distress and then along came these fanatical people. They put advertisements in the daily press, they inveighed against the hospital, they sent letters to all the subscribers, and they did their best to spoil the appeal for funds. They appealed to the ignorant and the unknowing by misrepresentations which might be called gross, and by that means they were destroying the flow of charitable funds. Yet let one of these propagandists himself be ill and all he had to do was to go to a private doctor and not suffer at all. They might take it that that was the general rule. He would give an example. They had the terrors of lockjaw in the war, when they found people dying of convulsions which could only be described as agonising, because they were convulsions right up to the point of death, and consciousness was preserved up to the point of death. They adopted the plan after most interesting investigations of using a serum against lockjaw. The effect on the mortality from tetanus in the war was that it came down to quite small proportions. Since the war it had been the rule for all well-ordered hospitals to have constantly in stock antitetanic serum, because street accidents were brought in from time to time, and it was the rule that directly a street accident was brought in antitetanic serum was injected. That was contrary to the principles of the antivivisectionist. There was a hospital in London where they would not use antitetanic serum. A street accident was brought in and they refused to give the serum and the patient died of lockjaw. What was more, two other patients subsequently died of lockjaw at this hospital; and they called that hospital a charity! He called it a place for propagandism and nothing more, and he hoped that King Edward's Fund would take note of this episode and would not give that hospital a certificate that it was a charity ready to treat the maimed and the wounded by the best methods known to science at the present time. At the same time as these poor people—the workers, who had no choice where they should be taken—were taken to this hospital, would the governors of the hospital or their children if they got an injury in a street accident go without antitetanic serum? Not at all; they would go home and call in their private doctor and it would be given. The fact was that it was an impossible situation. What it amounted to was that these people were practising their theories on the dog, only this time it was the human dog, and the world suffered thereby. He put it to their lordships that the health of the nation was a momentous matter not to be treated lightly, but to be treated seriously, and not made the playing-ground of vain imaginings, of misguided thought, and he asked the House to reject Lord Banbury's amendment.

Discussion on the Bill.

Lord **DANESFORT** asked the House not to allow Lord Dawson on an occasion like that to use the debate for the purpose of justifying the vivisection of stray dogs and introducing a totally irrelevant question into the discussion. He would certainly support the amendment.

The Earl of **STRADBROKE** (Parliamentary Secretary to the Ministry of Agriculture) said the clause under discussion which Lord Banbury desired to eliminate was inserted at the request of and after very long and careful consideration with various associations connected with the protection and care of dogs, and he thought they would agree that the clause as it now stood gave a stray dog a better chance. The societies that came and discussed the question of this clause and agreed upon it were the Royal Society for the Prevention of Cruelty to Animals, the Canine Defence League, the Battersea Home for Lost Dogs, and the Glasgow Dogs Home. Up to the present no objection had been lodged at the Government Department against this clause and therefore it was a surprise that this amendment should have been put down. It was the Government's view that the Bill would be better as it stood.

Lord **BANBURY** said that though he was against dogs being vivisected he was not an antivivisectionist. He did not raise the question. Having been defeated he had not attempted to bring on the Bill again in the House. If a noble lord wanted to buy a dog in a legitimate way the law allowed him to do so, but it was another thing to say that if he (Lord Banbury) lost his dog it was to be a chance for some person who found it to keep it a month and then sell it for vivisection.

The Marquess of **SALISBURY** (Lord Privy Seal) opposed the amendment. He said that if Lord Banbury had proposed to replace the clause with another which would have equally achieved his end and perhaps secured the particular view he held on vivisection, that would have been different, but what he did was to eviscerate from the Bill one of its essential clauses without putting anything in its place.

The amendment to omit the clause was rejected by 33 votes to 5. The Bill was read the third time and passed.

HOUSE OF COMMONS.

WEDNESDAY, JULY 11TH.

Coroners Act, 1887, Amendment.

Mr. **MORRIS** asked leave to bring in a Bill to amend the Coroners Act, 1887. He said that the object of the Bill was to amend Section 4 (3) of the 1887 Act, which related to the power of a coroner's jury to find a verdict of murder against the person accused. Subsection (3) indicated that a coroner's jury had to inquire who the deceased was, how, when, and where the deceased came by his death, and if he came by his death by murder or manslaughter, the persons, if any, who the jury found had been guilty of such murder or manslaughter. This amending Bill would cut out that part of the subsection with such consequential amendments as might be necessary in the remaining parts of the Act which related to the naming of the person found guilty of murder. The coroner's court was a very ancient court, and in the development of its history it had gradually come to occupy a very different position from that which it hitherto occupied in the administration of justice. The object of putting the provision in the Act originally was that the coroner's court was regarded as providing a collateral security for the prevention of crime. To-day, although a coroner's warrant could commit a person for trial and had the effect of an indictment, and was equivalent to the finding of a Grand Jury at the Assize Court, it was the invariable practice—although it was not necessary in law for the accused person to be brought before a magisterial court—for the magistrate to examine the case and come to a decision whether a prima facie case had been made out. It was not therefore necessary in the present circumstances to have an inquiry, especially under the conditions of examination conducted before the coroner's court. There were very strong objections to the present procedure. The coroner's court was not bound by the rules of evidence. Any evidence could be admitted. He was seeking in this Bill to provide that a coroner's jury should be limited to finding the cause of death alone. The Act of 1926 was unsatisfactory. The position was this: If a person had been arrested during the time of the coroner's inquest on a charge of murder the coroner should then suspend the inquest pending the conclusion of the trial. If the magistrates found there was no prima facie case they had a position where there was no conclusion to the criminal proceedings on indictment and the present law left it still open for the coroner to go on with the inquest and for the jury, notwithstanding the fact that the magistrates had thrown out the case, to find the person guilty of murder. That was a very illogical state of the law and for that reason he had brought in this amending Bill.

Leave to bring in the Bill was granted without a division.

Diagnosis of Small-pox Cases.

Mr. GROVES asked the Minister of Health whether, in view of the fact that the cases of small-pox occurring in London at the present time were so mild as to be hardly distinguishable from chicken-pox, and also of the fact that certain medical men believed they were not small-pox at all but alastrim or a new disease, he would issue fresh regulations permitting medical officers of health to leave them in their own homes and not put the patients to the discomfort and the ratepayers to the expense of having them removed to the small-pox hospital.—Mr. CHAMBERLAIN replied: I am advised that the small-pox now prevalent in this country should not be confused with chicken-pox or some new disease, and in view of the risks to the public health which would be involved by its further spread, I am not prepared to countenance the course suggested by the hon. Member.

THURSDAY, JULY 12TH.

Ex-Service Men and Medical Treatment.

Mr. STEPHEN asked the Minister of Pensions what remedy an ex-Service man had when he was recommended by the Ministry for treatment at home by his panel doctor and the panel doctor certified that treatment by the Ministry was necessary.—Major TRYON replied: Where it had been decided that a case was either not eligible for or did not require such a course of treatment as is provided by the Ministry of Pensions the case would fall to be dealt with under the ordinary arrangements available to insured persons under the National Health Insurance Acts.

Mr. STEPHEN: If the Minister decides that treatment is not possible and the man's panel doctor considers that treatment by the Ministry is necessary what step has the man then to take?

Major TRYON: It is quite clear that the Ministry cannot accept the doctrine that a panel doctor can decide for them. If the man has a grievance against the panel doctor the normal course would be for him to make an application to the insurance committee.

Mr. STEPHEN: But supposing the man has no grievance against his panel doctor; supposing that he considers that the advice of his panel doctor is right, is there not a medical referee whose opinion the Ministry and the panel doctor can be asked to accept? If there is not, will the Minister set up such a referee?

Major TRYON: No, Sir. The ordinary course must be followed. The case would be considered by the doctors of the Ministry of Pensions whose opinions must necessarily decide the action to be taken by the Ministry.

Mr. STEPHEN: Does the Minister say that the doctors of the Ministry must be the final arbiters in spite of the fact that equally eminent or more eminent medical men may say that the man ought to have treatment?

Major TRYON: No, Sir. The point is that the Ministry of Pensions must decide its own policy and not the panel doctor.

Mr. HARRIS: When doctors disagree would it not be possible to have an independent opinion from a specialist, because it is notorious that doctors often differ on medical points?

No further answer was given.

Medical Certification in a Case of Lead Poisoning.

Miss LAWRENCE asked the Secretary of State for the Home Department if his attention had been drawn to the case of Reginald Aubrey Wild, who contracted lead poisoning while working for Messrs. Locke, Lancaster, and W. W. and R. Johnson and Sons, Limited, of Millwall; whether he was aware that on application to the certifying surgeon for a certificate the same was refused, the certifying surgeon being the same doctor that was in the service of the employers; that the medical referee for the district, who formerly was the employer's doctor, had given a decision that the man was suffering from lead poisoning, but that he was not disabled; and whether, seeing that Mr. Wild was an in-patient in the London Hospital, suffering from lead poisoning, from April 20th until May 14th, after receiving a week's notice on April 15th, he would arrange for the man to be examined by a medical referee attached to another district as, until he was certified, no claim could be made for compensation.—Sir WILLIAM JOYNSON-HICKS replied: The decision of the medical referee under the Act is final, and I have no power to intervene in the manner suggested. I am, moreover, satisfied on inquiry that this case has been most carefully and conscientiously dealt with both by the certifying surgeon and by the medical referee, and I strongly deprecate the implication that these gentlemen, both of whom are medical practitioners of high standing, may have been influenced in carrying out their statutory duties by their connexion with these works. The certifying surgeon is responsible in his official capacity for the periodic examination of workers employed in lead processes under the Lead Compounds Regulations; he also, I understand, periodically examines the other workers and examines workmen newly employed, but has no other interest in the firm. The medical referee used to carry out some three years ago the periodic examinations required by the regulations, but he did this under special appointment from the Chief Inspector of Factories, and he was not, I am informed, otherwise engaged by the firm.

Miss LAWRENCE: In view of the fact that the medical referee for the district did not confirm the decision of the certifying surgeon, and that the certifying surgeon is employed in the manner detailed in the question, does not the right hon. gentleman think that some further inquiries should be made?

Sir W. JOYNSON-HICKS: I have made a very careful inquiry into the position of both these medical gentlemen and their connexion with the firm is very slight, and really, as far as the actual certificate of the medical referee is concerned under the Act that is final, and I have no power to intervene.

Mr. T. WILLIAMS: Is the right hon. gentleman aware that injured workmen practically all over the country have little or no confidence in certifying surgeons who are receiving large fees from employers and then acting for those same employers?

Sir W. JOYNSON-HICKS: In this case the suggestion cannot possibly be made. There is no question of a large fee being received from employers. As far as the general statement made by the hon. Member is concerned, I must really ask him to let me have at least a few of the details of these cases and then I will go into the matter at once, as he has made a very serious charge.

Miss LAWRENCE: I want to ask the right hon. gentlemen whether he has considered the conflicting medical opinions in this case and whether, in view of the conflict of medical evidence, it is not possible to arrange for another examination. The first doctor said that the man had lead poisoning, the second doctor said that he had lead poisoning, but was not disabled, and the third doctor, an independent doctor at the hospital, certified him as actually sound. In view of that conflict of medical opinion cannot the right hon. gentleman have another examination?

Sir W. JOYNSON-HICKS: I will get into communication with the third doctor who the hon. lady says is independent, and ask him to let me have a report on the case. (Cheers.)

Removal of Manchester Tuberculosis Clinic.

Sir THOMAS WATTS asked the Minister of Health if his attention had been called to the objections raised by the residents in the Oxford-road district of Manchester to the proposed removal of the tuberculosis clinic from Hardman-street to that district, and what action he intended to take.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. I proposed to arrange for a local inquiry before coming to a decision on this proposal.

Mr. HORE-BELISHA: Is it not a fact that in the debate in this House the unanimous view was expressed that this appeal tribunal should be established, and has the hon. and gallant gentleman considered this matter since that debate?

Lieut.-Colonel HEADLAM: I should dispute the fact that the opinion of the House was unanimous on that subject, and it is since that date that the decision has been arrived at.

Commander WILLIAMS asked what was the sickness in respect of which most of these people were invalided out?

Lieut.-Colonel HEADLAM: I cannot say off-hand, but I should say that it was tuberculosis.

Mr. HAYES: Was the matter considered by the Board of Admiralty or by an independent medical board?

Lieut.-Colonel HEADLAM: The Board of Admiralty considered the subject and consulted an independent medical board on the whole subject—not as to the tribunal, of course.

Compulsory Registration of State Nurses.

Mr. ERNEST BROWN asked the Minister of Health if it was the policy of the Government to make State registration compulsory for hospital nurses in Government establishments.—Mr. CHAMBERLAIN replied: The only Government establishment where nurses are employed for which I am responsible is the Rampton State Institution for Mental Defectives. So far as that establishment is concerned the answer to the question is in the negative.

MONDAY, JULY 16TH.

The Rating of Hospitals.

The House considered the Rating and Valuation (Apportionment) Bill on Report.

Mr. HARRIS moved a new clause providing that the expression "hospital hereditaments" should mean a hereditament occupied and used as a hospital, but should not include a hospital run for private profit or gain. He said that the work of the hospitals was an industry which had suffered severely since the war. During the last few years the strain on the voluntary system had been almost at breaking-point. Masses of people were implored to give money to the voluntary hospitals, and then it was handed back to the ratepayer in the form of taxation. Rates on the hospitals were tantamount to a tax on benevolence, on the sick poor, and on medical science.

Mr. CHAMBERLAIN (Minister of Health) pointed out that the Bill was not a plan for reconsidering the whole system with a view to deciding what kind of property might with advantage be relieved of rates. It was a special proposal which the Government were making for the stimulation of industry, and it was a far-fetched suggestion, indeed, to attempt to bring hospitals within the definition of industry. Although he had expressed a certain sympathy in this matter, he did not wish to be taken as having said that he was in favour of any particular scheme for derating hospitals. If the question were to be considered, they could not stop at hospitals. There were other kinds of property for which arguments on similar lines could be properly made, and he did not wish to be taken as having accepted the principle, as he had not given the question that consideration which would be necessary before he expressed a definite opinion. Certainly one recognised that there was a good case for the relief of the voluntary hospital, and with that he must content himself on that occasion. It might be that, on some future occasion, they would have some general scheme which would relieve various classes of property which were rated to-day, and on such a scheme the question of hospitals would properly find a place, but it was not appropriate to discuss it in a Bill designed to find a way to relieve industry.

Sir H. CAUTLEY pointed out that the assessment of the Sussex County Hospital had been put up to ten times what it was before. He hoped that, if he could, the Minister of Health would be able to do something for the hospitals under this Bill, or that he would exert some influence at once to put the provincial hospitals—although it applied also to the London hospitals—on some consistent footing throughout the country. Otherwise a very great number of them would have to shut down, because they could not possibly stand this enormous increase in their assessments.

Mr. GROVES said that if relief could be given to industries, surely the large London hospitals could be assisted. Many of the hospitals had had to close down a number of beds for lack of funds. They ought to make up their minds that the great medical and surgical institutions of the country were industries, because they really were shops wherein the bodies, and sometimes the minds, of the working population were repaired. Hospitals were a necessary adjunct to the industrial life of the community. One sweet thing about the hospitals was that they did not ask what a patient's politics were. In trying to restore people to health they were performing a function which was as essential to the well-being of the country as the work of any industry. He begged the Minister to reconsider his attitude to the amendment.

Mr. E. BROWN said that the amendment was within the scope of the Bill. The great hospitals and infirmaries were vitally linked up with the purposes of industry, and what was true of Glasgow, was true of Edinburgh and Leith, and of all the great cities up and down the country.

Dr. VERNON DAVIES said that he would have been very pleased if he could have accepted the arguments of the Opposition in favour of the amendment, but he could not persuade himself that the Bill was one for the relief of voluntary hospitals. The argument had been used that hospitals might be regarded as productive, in that they helped to produce medical men and nurses. But where was such an argument to stop? They might have relief of rates for theological colleges because they produced clergymen, and for political colleges because they were producing politicians. The question of the relief of hospitals was an entirely different one, and he did not see how it could come under this Bill, much as he would like it to do so, because the hospital question at present was undoubtedly serious. He believed that the Minister of Health had that fact well before him and was as anxious as anyone to deal with it. Attempts had been made to prove that breweries, which were to be relieved of rates, were a prolific cause of work for the hospitals. That might have been so in the past. In the old days it was not an uncommon thing to have patients in the hospitals as the result of alcoholic excess, but it was well known that there had been a great reduction in disease due to such excess. In his student days it was quite a common occurrence to come across cases of what were called "beer drinkers' heart," but at present they were the greatest rarities in clinical medicine. He believed, also, that cases of cirrhosis of the liver were markedly decreasing.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) asked the House to reject the amendment. He said that the voluntary system so far as the hospitals were concerned was not fading away but was very firmly based. A great measure of the support came from the workers concerned. Everyone would be glad to assist the voluntary system, but they had to consider whether this was an appropriate place to do so. This derating plan was a scheme to help productive industry and, if possible, lessen the burden of necessitous areas. So far as the voluntary hospitals were concerned, the Central Valuation Committee had made some valuable suggestions. If their advice was followed it would do away with many difficulties.

The clause was negatived by 219 votes to 110—majority 109.

TUESDAY, JULY 17TH.

Wireless for Medical Service in Shetland.

Sir ARCHIBALD SINCLAIR asked the Postmaster-General whether experiments in the establishment of communication by wireless between the island of Foula and the mainland of Shetland for medical service purposes had proved to be successful; and if so, whether, in view of the need for the improvement of communication, particularly on the ground of public health, between the island of Stroma and the mainland, the Government would consider making similar arrangements for the installation of wireless telephony on this island.—Sir W. MITCHELL-THOMSON replied: So far as I am aware, no experiments in the establishment of wireless communication between Foula and the mainland for medical purposes have yet taken place; and the second part of the question does not therefore arise.

Woman Lunacy Commissioner in Scotland.

Viscountess ASTOR asked the Secretary of State for Scotland what were the duties allocated to the lady assistant commissioner employed under the General Board of Control for Scotland.—Sir J. GILMOUR replied: The normal duties of the lady deputy commissioner consist of visiting lunatics and mental defectives under guardianship in private dwellings throughout Scotland. Occasionally she inspects lunatic wards of poorhouses.

Royal Commission on Local Government.

Mr. CRAWFURD asked the Minister of Health when the Report of the Royal Commission on Local Government was likely to be presented.—Sir KINGSLEY WOOD replied: It is understood that the Royal Commission hope to present a Report on certain questions within their terms of reference towards the beginning of November.

ENLARGEMENT OF ST. MARY'S HOSPITAL, PADDINGTON.—Lord Iveagh last week opened an extension which includes 60 additional beds and two operating suites, together with many domestic and sanitary improvements. The cost has been £60,000, of which £52,000 has been subscribed.

Medical News.

UNIVERSITY OF OXFORD.—At recent examinations the following candidates were successful in the undermentioned subjects:—

B.M. AND B.CH.

Medicine, Surgery and Obstetrics.—O. A. Beadle, M. V. Bhajekar, W. H. Brown, T. L. Davies, E. R. Holiday, A. J. Leslie-Spinks, J. M. A. Melly, A. E. Porritt, L. T. Ride, H. G. Wells, Florence H. Johnson, and Alice D. K. Peters.

Pathology.—A. D. Bell, T. M. Gledhill, R. D. Harding, H. C. Harley, Eugene Harvey, Francis Hawking, E. R. Holiday, K. N. Irvine, J. M. Lees, A. W. D. Leishman, J. C. Nicholson, N. C. Parfit, A. B. Stokes, R. L. H. Townsend, W. B. Williams, and Ruth Sandeman.

Materia Medica.—H. J. B. Atkins, F. W. Brown, N. P. Bruce, T. M. Davie, R. D. Harding, J. H. Hunt, J. E. Jenkins, C. J. King-Turner, J. C. Leedham-Green, A. W. D. Leishman, R. C. MacKeith, J. N. O'Reilly, R. S. B. Pearson, B. T. Squires, A. B. Stokes, W. S. Tegner, H. A. Treble, H. C. Wadge, Olive M. Capper Johnson, Winifred Mercer, and Elspeth W. Smellie.

Forensic Medicine and Hygiene.—M. V. Bhajekar, George Campbell, B. R. Caygill, R. M. J. Harper, E. R. Holiday, F. G. Parker, H. G. Pritchard, C. R. Salkeld, D. C. Shields, Florence H. Johnson, Caroline E. MacNeice, Alice D. K. Peters, and Joyce Wright.

The Master and Fellows of University College have awarded the Radcliffe Scholarship in Pharmacology to H. J. B. Atkins and J. H. Hunt. The Theodore Williams Scholarship in Pathology has been awarded to Frank Williams.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were approved:—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

Part II.—Edwin Amarasinghe, Oliver Chance, J. C. Coutts, F. J. Farr, D. L. Greig, D. A. Imrie, Leila K. Keatinge, D. F. Lawson, C. J. R. Morrison, H. C. Pillsbury, B. K. Roy, Tokue Takahashi, Edgar Thorpe, E. J. E. Topham, J. D. H. Wearing, and F. G. Wood.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the quarterly meeting of the Council held on July 12th Sir Berkeley Moynihan was re-elected President and Prof. W. Hey Groves and Mr. V. Warren Low were elected Vice-Presidents for the ensuing collegiate year. Mr. F. J. Steward, Prof. L. P. Gamgee, Mr. R. G. Hogarth, and Prof. R. E. Kelly, the newly elected members of Council, were introduced, and having made the necessary declarations took their seats in the Council. Mr. D. K. Cassels, M.A., who has been Assistant to the Secretary since 1924, was appointed Assistant Secretary to the College.

The following professors and lecturers were elected for the ensuing year:—

Hunterian Professors.—Sir Arthur Keith, Mr. Arthur H. Evans, Prof. G. E. Gask, Prof. C. A. Pannett, Mr. R. J. M. Love, Mr. C. P. G. Wakeley, and Mr. R. T. Payne.

Arris and Gale Lecturer.—Mr. Henry Albert Harris.

Erasmus Wilson Lecturers.—Mr. T. W. P. Lawrence and Mr. C. E. Shattock.

Arnott Demonstrator.—Sir Arthur Keith.

Diplomas of Member were conferred upon the following who have passed the necessary examinations and have complied with the by-laws: Nellie Brown, Westminster; H. G. Nimbalker, Bombay, Sheffield, and Middlesex.

The diploma of Fellow was also conferred upon J. C. B. Allen, Sydney, Guy's, and St. Bart.'s.

Licences in Dental Surgery were conferred upon the following candidates who have passed the requisite examinations and have complied with the by-laws of the College:—

D. B. Bergh, Guy's; S. Borson, London; D. J. Bull and S. G. Caston, Guy's; R. E. Clarke and Dorothy G. Coutts, King's Coll.; A. H. Crowley and E. M. Douglas, Guy's; D. H. A. Edmondson, Liverpool; W. Foster, Guy's; G. Gilol, Royal Dental; J. W. H. Jones, C. L. Knight, and H. M. Norman, Guy's; W. O'Reilly and D. V. Pandit, Univ. Coll.; H. J. Phillips and R. A. Phillips, Bristol; C. W. Pound, Guy's; R. A. Richardson, Royal Dental; D. E. C. Robertson, Guy's; W. S. Ross, Royal Dental; C. Seller, London; W. H. Shrigley, Guy's; R. S. Taylor, Royal Dental; F. C. Tomlyn, Guy's; F. Trainin and J. N. van der Merwe, Royal Dental; F. W. Walder, Univ. Coll.; W. J. Watson and G. H. S. Weir, Guy's.

The under-mentioned diplomas were conferred (jointly with the Royal College of Physicians) upon the following candidates:—

Diploma in Laryngology and Otology.—J. Acomb, N. Attygalle, H. K. Basu, N. E. H. Box, C. H. Carroll, G. D. Malhontra, T. G. Millar, A. A. Miller, G. W. Morey, W. J. Robertson, E. M. Steel, D. B. Sutton, and M. R. Wadia.

Diploma in Psychological Medicine.—Norah A. Haworth, R. Levinson, Agnes M. Macgown, J. J. B. Martin, A. Pool, and G. M. Tothill.

UNIVERSITY OF LEEDS.—At recent examinations the following candidates were successful:—

M.D.

A. Cannon, H. Sugare, and Gretta M. Wardle.

FINAL EXAMINATION FOR M.B., CH.B.

Part II.—S. G. Bedford, S. K. Foster, W. Greaves, Dorothy Halstead, P. Hampshire, L. B. Heseltine, C. R. Hiley, H. Hopkinson, J. R. O'Neill, T. L. Owen, N. Pyecroft, Doreen M. Robertshaw, Mary G. Shawe, L. Silman, L. Smith, J. O. Terry, Ivy R. Watson, and J. E. H. West.

Part III.—*L. Brill, *L. B. Heseltine, *J. H. Kahr, *V. P. Squire, C. R. Adgie, D. W. E. Burridge, H. W. Davis, L. Godlove, R. C. Hanson, A. Milner, J. P. O'Donnell, J. R. O'Neill, A. Reichlin, and J. E. H. West.

* Second-class honours.

D.P.H.

H. M. Holt.

FINAL EXAMINATION FOR L.D.S.

Part II.—W. Bedford, B. Taylor, and S. R. Woodcock.

UNIVERSITY OF LIVERPOOL.—At a graduation ceremony on July 7th medical degrees were conferred on candidates whose names appeared in our last issue (p. 100) as having passed the requisite examinations. The Ethel Boyce Fellowship in Gynæcology was awarded to Dr. Gwyneth Griffith; the Robert Gee Fellowship in Human Anatomy to Dr. E. N. Wardle; the J. W. Garrett International Fellowship in Bacteriology to Dr. J. S. Logan; the Holt Fellowship in Pathology to Dr. J. F. Galloway; the Holt Fellowship in Physiology to R. K. Bowes; the Johnston Colonial Fellowship in Biochemistry to Dr. L. Earlam; the Thelwall Thomas Fellowship in Surgical Pathology to Dr. R. Y. Dawbarn; the Samuels Memorial Scholarships to Dr. A. L. Kerr (Surgery) and Dr. M. M. Datnow (Obstetrics and Gynæcology); the John Rankin Fellowship in Anatomy to Dr. J. B. Rushton; the University Graduate Scholarship in Medicine to J. Libman; and the John Rankin Exhibition in Practical Anatomy to W. S. Diggle and T. L. Hughes.

UNIVERSITY OF MANCHESTER.—Dr. G. H. H. Booth has been appointed Demonstrator in Anatomy.—The Council have adopted regulations for the Dr. Robert Angus Smith Scholarship, which has been founded for the encouragement of research in sanitary science. The scholarship will be offered for the first time in June, 1929.

UNIVERSITY OF BELFAST.—The Senate of the Queen's University have appointed Dr. E. B. C. Mayrs to the chair of pharmacology and therapeutics, and Dr. F. M. Allen to be lecturer in materia medica and therapeutics.

INDUSTRIAL WELFARE SOCIETY.—At a lecture conference to be held by this society at Balliol College, Oxford, from Sept. 7th to 11th, an address on Nervous Disease and its Significance in Industry will be given by Dr. Millais Culpin.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.—An anonymous gift of £50,000 has been received by this Association, as a result of which the total sum collected in connexion with a special appeal exceeds £110,000.

The fourteenth annual conference will be held at the B.M.A. House, Tavistock-square, London, W.C., on Oct. 15th and 16th. Sir Arthur Stanley will preside, and the subjects of discussion will include the Occurrence of Tuberculosis among Primitive Peoples and the Principles underlying a Scheme of Antituberculosis Measure in Any Country. A number of Canadian tuberculosis officers visiting Europe will attend the conference and take part in the discussions. The sessions will be open to all persons interested in tuberculosis on payment of a fee. Names should be sent as soon as possible to the secretary, at 1, Gordon-square, London, W.C. 1.

WILLIAM HARVEY AND ABERDEEN.—At the June meeting of the Aberdeen Medico-Chirurgical Society Dr. Thomas Fraser took the chair, and Prof. J. MacWilliam, F.R.S., gave an address entitled "Reflections on Harvey's Work." He laid stress on the profound significance of Harvey's great achievement, not only in its obvious applications of fundamental importance in physiology and medicine, but also for the change which it led to in the general attitude of mind towards the problems of the animal organism, introducing a new spirit and method into the study of their relation to the forces and processes of the external world. Dr. W. Clark Souter read a paper on the visit to Aberdeen of Dr. William Harvey in 1641, when he was made an honorary burgess of the city. Dr. Souter showed a number of lantern slides on this and other Harveian topics, and a series of portraits of Harvey, giving his views on the authenticity and origin of the Harvey portrait in the society's possession, a gift from Sir Walter Farquhar in 1915.

MEMORIAL TO A LEEDS SURGEON.—A bas-relief to the memory of Lieut.-Colonel Harry Littlewood has just been unveiled at Leeds General Infirmary, of which he was surgeon from 1893 to 1921. It has been subscribed for by his colleagues, who have also contributed to the equipment of the instructional block at the infirmary. The portrait represents him in his uniform as administrator of the Second Northern General Hospital at Beckett's Park during the war. Colonel Littlewood had retired when the war broke out, and his war-time labours are believed to have shortened his life.

BIDDULPH GRANGE ORTHOPÆDIC HOSPITAL.—In June, 1924, the Prince of Wales opened Biddulph Grange, in North Staffordshire, as an orthopædic hospital for the county, but within less than a year it had to be closed for lack of financial support. It was subsequently purchased by the Lancashire County Council for a similar purpose, and has just been formally opened. The institution is intended to serve the Manchester area, from which it is no farther distant than if it were in some suitable part of Lancashire itself. There is accommodation for 85 children, and the building can readily be enlarged.

HOSPITALS IN CEYLON.—At present modern hospital facilities in Ceylon are obtainable only at the great Colombo General Hospital of some 700 beds. A committee appointed by the Executive Council of the island, which has been considering the situation, recommends that central hospitals should be established at Kandy, Galle, and seven other out-stations, and that, save in exceptional cases, no small hospitals should be maintained. It is further recommended that there should be an increase in the number of itinerant medical officers so that first-class surgical and medical resources should be available all over the island.

BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH.—At a recent meeting of the trustees Mr. W. G. A. Ormsby-Gore, M.P., Under Secretary of State for the Colonies, and the Earl of Onslow, Under Secretary of State for War, were appointed trustees in place of the late Sir Arthur Shipley, F.R.S., and the late Lord Cave. Sir James Kingston Fowler (hon. secretary) began his report by referring to the election of Dr. David Keilin—who had been the first student to hold successively Junior, Fourth Year, and Senior Beit Fellowships—to be an F.R.S. It was now very difficult, he said, to describe the work of the Fellows on medical and allied sciences in a form intelligible to those not engaged in them; but an exception might be made in the case of Dr. Edward Hindle's research on yellow fever. Dr. Hindle, who was appointed last year to the newly established Beit Fellowship in Tropical Medicine, began work in January, and "in the short period which has since elapsed has obtained results in the course of a research on yellow fever which give good ground for the belief that a vaccine has been discovered which will afford protection against that disease." He has shown "that a vaccine prepared from the livers of infected monkeys will protect a monkey from the effects of a dose of the virus ten thousand times as great as the fatal dose, and the monkey continues to be healthy and lively." It has still to be ascertained, said Sir James, what are the best methods of preparing and of administering the vaccine; what is the dose necessary to afford protection; how long the protection will last; and whether the results obtained with monkeys are also true of man.

It was stated that Mr. Alan Sterling Parkes, D.Sc., and Miss Honor Bridget Fell had been promoted from Fourth Year Fellowships to Senior Fellowships. The following appointments to Junior Fellowships are announced for research into the subjects indicated:—Juda Hirsch Quastel, D.Sc. Lond., Fellow of Trinity College, Cambridge: extension of work on the chemistry of bacteria and of complement fixation. Percival Walter Clutterbuck, Ph.D. Manch., F.I.C., assistant lecturer in chemical physiology in the University of Birmingham: nature and function of the succinoxydase system of muscle and investigation of the enzymic systems concerned in carbohydrate metabolism. Bryan Harold Cabot Matthews, B.A. Camb., at present demonstrating in physiology at the University of Cambridge: conduction in sensory nerve-fibres, and the characteristics of sensory end-organs. Douglas Roy McCullagh, M.Sc. Manitoba, at present working at the Sir W. Dunn Institute of Biochemistry, Cambridge: studies in carbohydrate metabolism. Wallace Russell Aykroyd, M.D. Dub., now doing research in the School of Physiology, Trinity College, Dublin: an inquiry, at the Lister Institute, London, and in Newfoundland, into deficiency diseases and their relation to diet.

Correspondence concerning the Fund should be addressed to the hon. secretary at 35, Clarges-street, London, W.

"RE-ENDOWMENT" OF GUY'S HOSPITAL.—The treasurer's annual report states that "the time has come for the re-endowment" of the hospital, the adverse balance of income and expenditure having steadily accumulated, till it now exceeds £100,000. "The great success of the hospital during two centuries has very largely sprung from the freedom from financial anxieties of her administrators," and the governors feel that the position must be faced. Re-endowment, it is pointed out, involves the provision of half a million of money, which "constitutes a very serious call to the wealthy." Meanwhile it is recorded that the reconstruction of certain wards has been completed, and that 10 per cent. has been added to the accommodation. Last year 10,795 patients passed through the wards, which caused an appreciable reduction in the waiting list. The average stay of each patient, both medical and surgical, was reduced by rather more than a day. Out-patients made the enormous total of 537,676 attendances, at a cost of 1s. 7½d. per attendance. The provision of the new out-patient department is being delayed by difficulties in clearing the site for the extension.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, July 23rd.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, July 23rd.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Simmonds: [illegible] Wards.

TUESDAY.—10 A.M., Medic[illegible] Shaw: 2 P.M., Mr. Addison: [illegible] Medical Out-patients.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. [illegible] 2 P.M., 10 A.M., Dr. Owen: [illegible] Dr. Scott Pinchin: [illegible]ological [illegible]

THURSDAY.—10 A.M., I[illegible]rations. Department. 2 P.M., [illegible] Genito-Urinary Department. 2 P.M., Mr. MacDonald: [illegible] Medical Wards. 12 noon,

FRIDAY.—10 A.M., D[illegible] 2 P.M., Mr. Dr. Ironside: [illegible] Sinclair: Surgic[illegible] Nose and Ear

SATURDAY.—9 A.M., [illegible] Operations. 10 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.

Daily 10 A.M., to 5 P.M., Saturdays 10 A.M., to 1 P.M., Medical, Surgical and Special Departments. Operations, Anæsthetic Course, &c.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

The Lecture arranged to be given by Sir Thomas Carey Evans on July 26th, has been indefinitely postponed owing to his unavoidable absence from London.

Appointments.

GOUGH, J. H. Harley, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Surgeon to the Ear, Nose and Throat Department of the Royal West Sussex Hospital, Chichester.

MURPHY, D., M.B., B.Ch. N.U.I., Medical Examiner of Emigrants, Canadian Government.

SHARP, C. G. K., M.D., Ch.B. Leeds, School Oculist, West Riding.

THOMPSON, J. A., M.B., Ch.B. Edin., Medical Inspector, West Riding Schools.

WHITE, C. F., M.B., Ch.B., D.P.H., Medical Officer of Health for the Port of London.

Vacancies.

For further information refer to the advertisement columns.

Bangor, Carnarvonshire and Anglesey Infirmary.—H.S. £200.

Bath, Royal United Hospital.—Asst. H.S. £100.

Birmingham, Birmingham and Midland Ear and Throat Hospital. 2nd H.S. At rate of £150.

Birmingham, Children's Hospital.—Res. M.O. £175. Also Cas. O. £250.

Birmingham University.—Walter Myers Travelling Studentship. £300.

Blackburn County Borough.—Asst. Dentist. £475.

Bradford, Royal Eye and Ear Hospital.—Res. H.S. £120. Also H.S. £120.
Cambridge, Addenbrooke's Hospital.—H.P. At rate of £130.
Chesterfield, Chesterfield and North Derbyshire Royal Hospital.—Cas. H.S. At rate of £100.
Dublin, St. Vincent's Hospital.—Hon. Asst. Surgeon.
Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.
Exeter, Royal Devon and Exeter Hospital.—H.S. At rate of £130.
[illegible] *pital.*—Jun. Asst. M.O. £300.
[illegible] District M.O. Also Public Vacci-
[illegible] pectively.
Hastings, Royal East Sussex Hospital.—Hon. Surgeon.
Hertford, Hertford County Hospital.—H.P. At rate of £150.
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150.
Liverpool, Liverpool and District Hospital, &c.—H.P.
Liverpool University.—Alfred Jones Chair of Tropical Medicine. £1000.
Liverpool, Walton Institution, Rice-lane.—Res. Asst. M.O. £200.
London Hospital Medical College, Mile End, E.—Assistantship in the Department of Physiology. £400.
Maidstone, Kent County Mental Hospital.—Med. Supt. £1000.
Maidstone, Kent County Ophthalmic and Aural Hospital.—Aural H.S. At rate of £200.
Mexborough, Montagu Hospital.—Hon. Supervisory Radiologist.
Newcastle-on-Tyne, Royal Victoria Infirmary.—Res. M.O. £250. Also Surgical Reg. At rate of £100.
Northampton, County Borough.—Asst. M.O. £600.
Norwich, Norfolk and Norwich Hospital.—H.S. £120.
Nottingham General Hospital.—Res. Cas. O. At rate of £200.
Oldham, County Borough.—Asst. Schools M.O. £600.
Preston and County of Lancaster Royal Infirmary.—H.P. and H.S. £190 and £150 respectively.
Queen's Hospital for Children, Hackney-road, E.—Cas. O. At rate of £100.
Richmond, Surrey, Royal Hospital.—Hon. Asst. Radiologist, also Jun. H.S. £100.
Rotherham, Rotherham Hospital.—H.P. £180.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. M.O. At rate of £175.
Scarborough, Scarborough Hospital and Dispensary.—Two H.S.'s. Each at rate of £126.
[illegible] *rmary.*—H.S. At rate of £160.
[illegible] *ndon.*—Examiner in Midwifery.
[illegible] *Laboratory.*—Bacteriologist. 10 gns. per week.
Taunton, Taunton and Somerset Hospital.—Sen. House M.O. £150.
Woolwich and District War Memorial Hospital, Shooters' Hill, S.E.—Sen. H.S., also H.P. Each at £125.
Worcester County and City Mental Hospital, Powick, near Worcester.—Jun. Asst. M.O. £300.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Linlithgow (West Lothian).

A vacancy for a Medical Referee under the Workmen's Compensation Act, for the district of the Clerkenwell County Court (Circuit No. 41) is announced. Applications from Physicians should reach the Private Secretary, Home Office, Whitehall, S.W.1., not later than August 9th.

Births, Marriages, and Deaths.

BIRTHS.

DUNN.—On July 10th, at Red House, South Farnborough, the wife of Dr. G. Hunter Dunn, of a son.

GRIFFITH.—On July 13th, at Paradise House, Cambridge, the wife of A. Stanley Griffith, M.D., of a son.

MARRIAGES.

HORSFALL—ADAMS.—On July 7th, at the Church of St. Mary the Virgin, Ewell, Thomas Miles Moss Horsfall, M.D., to Phyllis Mary, only daughter of the late Mr. Herbert E. Adams and Mrs. Adams, of Hendford, Ewell, Surrey.

DEATHS.

KAY.—On July 9th, at Lymington, Bt.-Colonel A. G. Kay, R.A.M.C. (retired), aged 74.

KERR.—On July 13th, at 70, Scarisbrick New-road, Southport, Nettie Russell Donald, wife of Dr. James R. Kerr.

NEWBY.—On July 7th at Broad Park-avenue, Ilfracombe, Charles Henry Newby, F.R.C.S. Eng., aged 78.

STAPLES.—On July 11th, at St. Trinian, Walpole-gardens, Strawberry-hill, peacefully in his sleep, Lieut.-Colonel Francis Patrick Staples, R.A.M.C., (retired).

WHITEHEAD.—On July 11th, in London, after an operation, Col. J. H. Whitehead, D.S.O., M.R.C.S., L.R.C.P., of Plains, Natal, S. Africa, aged 58.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET." VOL. I., 1928.

THE Index and Title-page to Vol. I., 1928, which was completed with the issue of June 30th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

THE NATIONAL INSTITUTE FOR THE DEAF.

THE fourth annual meeting of the National Institute for the Deaf was held at the Central Hall, Westminster, on July 17th, when the President, Lord Charnwood, was in the chair. Before the actual business of the meeting commenced, the Chairman voiced the unanimous feelings of those present by expressing the deepest sympathy with the Secretary, Mr. A. J. Story, in his recent bereavement, the sudden death of his wife.

In moving the adoption of the report of the committee. for the year ending March 31st last, Lord Charnwood emphasised the fact that an appreciable number of deaf people would be greatly benefited if facilities for a higher standard of education were provided for them, while the community would also gain. He pointed to the danger that children who were deaf might be classed among the mentally defective, owing to lack of insufficient arrangements on the part of State authorities, and some institution of national scope, he said, was needed to help the deaf after the education period. He referred to his recent effort in the House of Lords, with the support of the Duke of Montrose and the Archbishop of Canterbury, to induce the Government to set up some body to consider the whole question of the education of the deaf, and of their future employment for the good of the community. He hoped for better results in future efforts along this line, and expressed his gratitude to THE LANCET for the way in which it had supported the cause of the deaf.

Mr. Walter G. Yates, the hon. treasurer, then submitted the financial statement for the year ending March 31st. the main feature of which, he said, was that much of the money that had been obtained by special appeal had been used to make up deficiencies, and he pleaded for further donations, as the ordinary income was insufficient to meet expenses. Much propaganda work had to be done, and the results obtained by their small staff were really phenomenal.

Mr. M. Birley, Chairman of the Executive Committee, seconded the adoption of the report and of the financial statement, and the necessary motion was carried unanimously.

The Duke of Montrose said that in the name of social legislation the Government practically fed, clothed, educated, and nursed a large proportion of the people of the country. Something like one person in 30, he understood, was in receipt of State alimony of some kind in the name of social welfare, and he thought the time had arrived when something more should be done for the deaf. The only department of the Government which seemed to be concerned with the deaf was the Board of Education, and they were only interested in the education of children up to 16, or, in some cases, 18 years. It was 40 years since any Government Department had made an inquiry into the position of the deaf, and it was time that there should be an examination as to their welfare. Referring to the debate on Lord Charnwood's motion in the House of Lords for a Departmental inquiry, he stigmatised the proceedings as discreditable to the House, while he advocated the formation of vocational centres for the deaf and the encouragement of craft-work in order that as many deaf subjects as possible—and he thought the number would be very large—might become self-supporting. He moved:—

> "That having regard to the grave social and industrial hardships caused by deafness in the lives of large numbers of adolescent and adult persons who were born deaf or have become so, and to the fact that no official inquiry into the results (in the terms of improved social and industrial well-being) of large public expenditures in their education has ever been held, this meeting is strongly of opinion that the time has arrived when a complete investigation into the conditions and needs of these deaf and dumb and deafened persons should be made.
>
> "And, further, that this meeting urgently calls upon the Government to make such an investigation by means of a Departmental Committee, or otherwise, at an early date."

Colonel F. E. Fremantle, M.P., who seconded the motion, said that something like one-third of the adult population of the country had some difficulty of hearing, so that, apart from the cases with which the National Institute dealt, there was a huge number of people who should be personally sympathetic, and consequently be a potential source of help to the Institute. He quoted statistics which suggested the enormous loss to the country in personnel which defects of hearing caused, and thought that from the economical point of view the country might be losing as much as two million pounds a year through neglecting to employ the deaf suitably. He cited also figures contained in a contribution to THE LANCET by Squadron-Leader David Ranken dealing with the physical examination of airmen, and showing that of the total percentage of rejected recruits from the Air Service for all reasons it might be estimated that aural disease affected 2·8 per cent. of that part of the population likely to present themselves for enrolment. From figures supplied from one particular London school for deaf boys between the years 1902 and 1928, and dealing with 737 boys who had left, he said that 89 per cent. of these were in employment and following a trade which they had learned at school, showing the high degree of efficiency which could follow training. It was obvious that the country ought to go ahead in that direction, and he was glad that the Institute was attempting to take the matter up on a national scale, and obtain the hearing of the Government.

Sir Squire Sprigge moved :—

> "That the best thanks of the meeting be given to the President, the Executive Committee, the hon. Treasurer, hon. Solicitors, hon. Auditors, and to Mr. C. M. R. Balbi, A.M.I.E.E., hon. consulting electrical expert, for their services during the year, and that all these gentlemen be requested to act in their several capacities during the ensuing year."

The motion was carried unanimously and the meeting terminated with a cordial vote of thanks to the chairman and speakers.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—Will you once again give us the opportunity of drawing the attention of your readers to this Fund, which may well claim to render good service to our poorer sisters, and so to the whole community. The change wrought in these pale Londoners in a few days is almost incredible, save to the eye-witness. Good food and plenty of it, rest on the beach or in the fresh country fields, and above all, freedom from care—knowing their holiday is paid for before they go—work wonders. There are now hundreds of girls hoping to be sent away during the next few weeks. Fresh applications come in daily, but we have not enough funds to send half the number at present. Many of the applicants have been saving out of their earnings week by week since the beginning of the year, towards their share of the cost of their holiday. Are they to be denied this pittance of a holiday, looked upon by most as a bare necessity? Are they, who for at least 50 weeks of the year have to go to their long and monotonous day's work in all weathers, to be denied health-giving air and surroundings during the other few days? Could your generous readers see, but for a moment, that long procession of hard-working and, alas! often worn, and pale girls coming to pay their savings week by week, for months before their holiday, they could surely not deny them the balance which would make it a certainty. This Fund helps chiefly the poorest class of factory workers, most of them are the main support, too, of their families. Subscriptions and donations will be thankfully received and acknowledged by the hon. treasurer, Mrs. Slater, or Miss Canney, 75, Lamb's Conduit-street, London, W.C. 1.

We are, Sir, yours faithfully,

(Signed) ALBERTA SANDWICH, A. F. LONDON,
MARY SCHARLIEB, J. F. GREEN,
LILIAN BRAITHWAITE, Chairman.

July 16th, 1928.

HEALTH INSTRUCTION FOR MISSIONARIES.

THE fourth edition of a pamphlet entitled "Health Instructions for Missionaries in the Tropics," has been issued by the Association of Medical Officers of Missionary Societies (1, Farnley-road, London, E. 4), price 4*d*. Various additions, including illustrations of some of the disease-carrying insects, have been made since the last edition was published in 1922 and the whole text has been revised. The booklet is intended for study before going abroad, and for reference when in the tropics.

THE ALMONER'S WORK AT AN EYE HOSPITAL.

A SHORT report by the Lady Almoner of Moorfields[1] gives a vivid picture of the routine work in her department. Children with phlyctenular keratitis, blepharitis, or interstitial keratitis who fail to respond to the surgeon's treatment are often found to be living in unhygienic conditions. A prolonged convalescence in a suitable institution often does far more to help them than continued attendance at the hospital. A child may be sent to Mayfield Ophthalmic Convalescent Home where there is skilled ophthalmic nursing, or to Swanley Ophthalmia Schools; in other cases the visits of a district nurse at the home may be effective. Extra food may be required, when the coöperation of a charitable society, such as the Invalid Children's Aid Association, may be applied for. Children suffering from interstitial keratitis may have to be transferred for treatment at one of the V.D. centres. For cases of progressive myopia, the surgeon may recommend either a myope school or "easy treatment" at school. Without the social service worker there would be nobody to see that this recommendation was carried out. Another class of case that needs the help of the social worker is that of the blind or partially blind, for whom surgical treatment can do no more. Even infants under 5 may benefit by a sojourn at a "sunshine home" whence they return not quite so helpless as before. There are schools for the blind for older children, workshops for adults, and pensions for those over 50, and in all these cases the almoner's business is to put the patient in touch with the appropriate voluntary association or Government department. Her work is an essential supplement to that of the surgeon.

PSYCHIATRY IN INDIA.

THE European Mental Hospital at Ranchi has issued a report on its progress from 1924–1926. The number of patients admitted and discharged during the triennium was 199 and 124 respectively, and the total mortality was 22; 16, 9, and 37 voluntary boarders were received in each of the three years. The admission of three mental defectives brought up the question of State care of these children, but the Government decided that it could not yet cope with so vast a problem. The medical superintendent, Lieut.-Colonel O. A. R. Berkeley-Hill, is doing his best to arrange a pioneer institution to take 20 children. The value of occupational therapy for mentally disordered patients is recognised at Ranchi, and special buildings are to be provided for this purpose. A games and sports department is actively at work, and a swimming and boating lake has been constructed by damming a valley in the neighbourhood. A golfer-patient has discovered and laid out a nine-hole course. After-care of discharged patients is a difficult problem in India, but Toc H and the League of Women Workers have rendered invaluable service of this kind in Calcutta. Investigations into the production of aseptic meningitis by injection of horse serum have been carried out with the aid of the dhobi's pony, and will be reported on next year.

We wish Lieut.-Colonel Berkeley-Hill every success in his exacting task.

"MANSON HOUSE."

THE suggestion that Manson House should be the name of the new headquarters of the Royal Society of Tropical Medicine and Hygiene has already given rise to confusion, as the word may be mis-heard as "mansion house." Colonel Clayton Lane's plea that the building should be called "Patrick Manson House" is supported by the fact that we mis-printed "mansion" as "manson" in his last letter (THE LANCET, July 14th, p. 95), thus committing the two possible errors in consecutive issues of this journal. Whilst purists may regard their pronunciation of this inverted shibboleth as beyond criticism, it can evidently cause inconvenience even to those whose intentions are excellent.

CHILDREN AND THE SEASIDE HOLIDAY.

THE problem of the children is always an anxious one for parents, but never is this more so than during the month of August, when the schools are closed and everyone is holidaying. At Hastings the corporation has engaged a staff-sergeant whose duty during August will be to amuse the children on the sands with organised games, and at the same time to give them instruction in physical drill. The value of this excellent scheme is increased by the provision of a tent which will play the part of a creche.

CONFECTIONERY.

THE Chocolate and Confectionery Exhibition, held at Olympia last week, was not without medical interest. Wholesome chocolates and pure boiled sweets can be very useful, as well as popular, prescriptions at the proper time, while toffees and mints play their part respectively in the treatment of pharyngeal cough and minor digestive disorders. Chocolate is a very valuable vehicle for milk, and the bulk of Cadbury's "Dairy Milk" is manufactured in the summer when the milk-supply is ample and irradiated. For those who like a coffee flavour, Terry's new "Café au lait" chocolate can be recommended. De Villars specialise in plain chocolate flavoured with all sorts of surprising things—orange, raspberry, and currant, for instance. Fox's "Glacier Mints" and barley sugar are well known, but not everybody knows that this firm also markets a eucalyptus and menthol sweet for winter colds and throats. Van Houten's cocoa is a household word; their bitter chocolate is an excellent food-medium for those who do not like a sweetmeat. For wholesome assortments, the Dutch firms, such as Dioste and Rademaker, should not be forgotten. This was the first exhibition organised by the chocolate makers alone.

An Address

ON

SOME REACTIONS AND A RETROSPECT

Delivered at the Annual Meeting of the British Medical Association at Cardiff on Tuesday, July 24th,

BY SIR EWEN MACLEAN, M.D., F.R.S. EDIN., F.R.C.P. LOND., HON. F.A.C.S.,

PRESIDENT OF THE ASSOCIATION; PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

[AFTER reviewing the public work of the Association since it last assembled in Cardiff 43 years ago, the lecturer continued :—]

ANCIENT CYMRIC MEDICINE.

Casting back to more distant times, the exhibit which, by the courtesy of the authorities, has been set up in the Library of the National Museum shows, I think, that "Antient Cymric" medicine affords a most attractive field for study and research, and I am indebted to my friend Dr. Roland Williams for many interesting observations and gleanings in this connexion.

Handed down from very remote times, a glimmering of medical science would seem to have existed in pre-Celtic and Celtic Britain. It is difficult to conceive, for instance, that the new Stone Age and the Bronze Age, rich as they were in the pioneer achievements of civilisation, should have been lacking entirely in some form of indigenous medical lore. Possibly, too, those very early traders from the older Mediterranean civilisations who came to seek tin from Cornwall left behind them something of the healing traditions of other lands. At any rate, however such knowledge may have accrued, there are some grounds for crediting the Druids with perhaps a greater preoccupation with medicine than was usual in a primitive priestcraft. The Greek geographer Strabo (born about 60 B.C.) has left it on record that the "soothsayers are sacrificers and physiologists; the Druids, in addition to physiology, practise ethic philosophy." Pliny gave a brief account of a Druidic *Materia Medica* in which the mistletoe or "All-Heal" was held in highest esteem. Presumably, too, the British Druids were similar in type to the Druids of Gaul, to whose advanced "knowledge of the Laws of Nature" Cicero referred. It is interesting to note that, as preventives to ill health, the Druids prescribed *cheerfulness, temperance, exercise, and early rising*, qualities and practices which—shall we say?—have remained characteristics of the Cymry to the present day. Albeit, another of the Druidical maxims, asserting that "Money lent in this world will be repaid in the next," would not, I fear, in practice to-day, rank as a gilt-edged security.

After the Druids came the Romans. Soldiers, engineers, administrators as they were in the main, we do not know what legacy they left behind them towards the building up of a native medical tradition in Wales, but it is legitimate to surmise that at least some elements of the lore of Hippocrates and the great Greek medical tradition may have made its way into Britain with the legions, and, once implanted there, may have lingered, as the *language* of the legionaries lingered after their departure, in Cornwall, in Cumberland, and in Wales. It is a significant fact that the modern Welsh word for a physician, the word *meddyg*, goes back directly to Roman times, being derived from the Latin *medicus*, and occurring first in its Welsh form in the old Cornish vocabularies.

After Rome, the welter of the Dark Ages—a period dark to the historian everywhere in Europe, but darkened still more in Wales owing to the distrust to which many of the manuscripts relating to the period are subject. Not until the beginning of the tenth century and the codification of Welsh Tribal Law about that time do we come upon reliable information regarding the profession of medicine.

A thousand years ago King Hywel the Good caused the laws of Wales to be codified, and it is in these codes that we get the first authentic glimpses of our profession and the manner of men who practised it in tenth-century Wales. This monarch had a court physician who was given place and prestige in his presence, had a grant of free land and a horse, and received his linen clothing from the Queen and his woollen clothing from the King. His seat in the hall within the palace was at the base of a pillar near to the King, and his lodging was with the chief of the household. It was his duty to administer medicine without charge to all within the palace, and to the chief of the household. It would appear that he was a whole-time officer, with intervals when, on the basis of a moderate tariff, he was allowed to enjoy the stimulating freedom of private practice. He had to accompany the armies, but ordinarily he was never to leave the palace without the King's permission, when he was free to take any road or route with the messenger of the sick. In these days it was lawful for anyone to take another's horse to procure a medical man for a person in danger, without being required to make amends. The same principle applied to-day in respect to motor-cars might lead to serious misunderstandings.

The chief interests of these early codes, from a medical point of view, lies in the way they assessed legal damages for injuries and laid down standard fees for treatment. The thumbnail, for instance, was worth 30 pence. One front tooth was equal to a finger; one molar tooth to a thumb.

MEDIÆVAL TRADITIONS.

The old laws are interesting as showing us something of the state of the Welsh *meddyg* under the Welsh tribal system in the tenth century. The eleventh century brought with it great changes in Welsh history. A great new formative influence came then into the life of Wales—that was the Norman. The Norman affected profoundly the whole course of Welsh life and politics. Under the walls of his castles there grew up townships, markets, forts. Once more, as in the days of the early wandering Celtic missionaries, Wales came into touch with the rest of Europe and the world. For not in Wales and England only, but in Ireland, in France, in Spain, in Sicily, in Palestine even, on the threshold of immemorial East—there too were the castles of the Norman. Pilgrim and Crusader, merchant, monk and friar, errant knight and troubadour, all whose activities helped to render knowledge fluid and international throughout the Holy Roman Empire, must have helped towards the building up of a native medical tradition in mediæval Wales, a tradition which has left behind as its monument a fourteenth century manuscript, the older of the two manuscripts known as the "Books of the Physicians of the Myddfai."

It was but natural that the tradition of the physicians of the Myddfai in mediæval Wales should trace its origin back to the fountain head of a legend.

In the fastnesses of the wild Fan Mountains of Carmarthenshire there is hidden away a small lake known as Llyn-y-Fan Fash. Long ago, so the legend runs, a shepherd boy named Gwyn was tending his flock on the shore of the lake when a most beautiful maiden emerged from the mirrored surface of the water. After many complications, which are so essential to a fairy tale, Gwyn and the maiden of the lake became man and wife. Three sons were born to them, but after a time the maiden disappeared again into the depths of the lake, taking with her her faery dowry of cattle and chattels. At a later day, however, she reappeared to her three sons, who kept vigil for her on the shore. The eldest son, Rhiwallon, she led aside to Pant-y-Meddygon (the Physicians' Hollow); there she revealed to him the properties of the medicinal plants and herbs which grew around them, and called upon him to dedicate himself to the art of healing. This Rhiwallon did, so that he became the physician to Rhys Grug, Lord of Llandovery and Dynevor. Tradition claims, too, that the descendants of Rhiwallon practised their art at Myddfai in unbroken lineage until the end of the eighteenth century.

Such, in brief, is the story of the physicians of Myddfai.

Interesting though these earlier figures may be, however, it is only after the Renaissance had rejuvenated Wales that we come upon the beginnings of a really brood-culture among Welsh physicians. Although not one of the outstanding physicians of Wales in Tudor and early Jacobean times had any claim to be compared to a Sydenham or a Harvey, they were yet figures commanding interest and respect in other ways. Educated, most of them that we know of, at the older English universities, their medical writings and their medical beliefs were, for their day and generation, reasonable and scientific. One striking characteristic which many of them had in common was the great breadth of their culture and their scholarly achievements in other arts besides medicine. Thus Phaer of Pilgeiran was one of the first great Elizabethan translators of the classics, while to Robert Recorde of Tenby we owe the introduction of the study of algebra into this country.

Time does not permit to follow the fortunes of the Welsh *meddyg* through the seventeenth and eighteenth centuries. Something of their ubiquity and prominence may be gathered from the fact that the two surgeons on board Captain Cook's ship the *Resolution* in 1777 were Welshmen—Robert Davies of Wyddgrug, and David Samuel of Denbigh. Samuel later became surgeon of the *Discovery*, and he may have suggested to his captain some of the latter's very enlightened ideas regarding the relationship of scurvy to diet. At any rate, Samuel was a scientifically minded man, as shown by his treatise on the introduction of certain diseases among the South Sea Islanders. "He was," so wrote one of his contemporaries, "extremely irritable, but one of those hearty fellows we expect a sailor to have been."

But however true it may be that the past, even the distant past, is ever with us and must tincture our every thought and deed, the blend of the present and the immediate future is the main incentive to individual and corporate action.

HEALTH ORGANISATION IN RECENT TIMES.

The population of the world to-day is many times greater than it was a thousand years ago, and over the average of years Mother Earth shows no signs of failing to respond to the food and other requirements of her increased family of humans. *Correspondingly*, however, much more work has to be done by these humans in order to extract and prepare these requirements. Effective work involves a sufficient measure of health, and hence, perhaps, one factor at least of the instinctively higher regard for the health of the individual and of the community which is so marked a social feature of the day.

The demand is insistent, and from the nature of the case the supply can never wholly meet it. But quite wonderful achievements have been registered by organisation and scientific discovery. At the same time those who know must know how much more remains to be done.

A sign of the time, that enactment of outstanding importance, the National Health Insurance Act, 1911, which provides domiciliary medical attendance for, say, 16 million of the 45 million of the population, has profoundly modified and to a significant extent refocused the conditions of the great bulk of medical practice in this country.

Piloted with great ability and energy through a half-reluctant House of Commons by Mr. Lloyd George, the then Chancellor of the Exchequer, menaced by vested and otherwise disturbed interests, this colossal measure came into operation in the early days o January, 1913. The unavoidably complex machiner of so far-reaching an Act was but as yet in the stag of graduating through the inevitable jolts and ja when the cataclysm of the great war and the disabilities of demobilisation intervened as a further strai on administration.

It says much for the administrative staff and eve more for the 15,000 medical practitioners acceptin service under the Act that, as set forth in the Memorandum of Evidence submitted by the British Medica Association to the Royal Commission on Nationa Health Insurance, both the Representative Body o the Association and the Conference of Representative of Local Medical and Panel Committees agreed "tha the measure of success which had attended th experiment of providing medical benefit under th National Health Insurance Acts system has bee sufficient to justify the profession in uniting to ensur the continuance and improvement of an insuranc system."

It is demonstrable that insured persons under th Act, taken as a whole, are provided with a bette grade of medical service than were their equivalent before its inception. But of the making of regulation there is no end, and the officials concerned, and *certainly* the busy practitioner, may well be forgive if, on occasion, a lapse of memory leads to executive error. It would be a real boon to the insurance *practitioners, to the officials, and to the insure* persons, and would prevent many mistakes and misunderstandings, if someone—it would admittedl *require little short of a genius*—would *intelligibl* collate the multitude of regulations.

Under the Act as it stands much more could have been done, and should be done, in the *matter* o wise propaganda directed to the means of preserving health and of preventing disease; but, taking the Act in general, with its *many inherent administrative* difficulties, it can be said that the major provisions are being sympathetically and effectively implemented. But the degree of success so *far attained in* itsel calls for further and fuller developments, which in due course should be equally available for all insured *persons regardless of their membership of any* particular society.

Such further provisions should include complete consultant and specialist advice and *treatment*, and, under conditions, nursing and massage. Various salient advances by some of the approved societies have already been made *into the region* of these developments, notably in the form of dental, ophthalmic, or institutional extra benefits, and the experience and results *accruing* will, doubtless, ultimately encourage an advancement of the line, as indicated in recent enactments by Parliament.

In such logical and, indeed, inevitable developments of the health insurance scheme, stage by stage being added after full consideration of the reasonable *interests of those concerned*, I for one fail to see the risk of any sudden ultimate transmutation to a whole-time State medical service, with its connoted and *handicapping officialism* and sacrifice of personal freedom.

[At this point the lecturer briefly surveyed the *advances of medicine and surgery* since the Association last assembled in Cardiff. On the crest of the wave of recent years, he said, ride prominently *the bacteriological and biochemical* discoveries, the latter even overshadowing the former, as witness the new science of the endocrines, the chemistry of *body fluids*, the *functions of organs* as expressed *in their* influence on the composition of the blood—for example, liver, spleen, and, lastly, the *vitamins*. Such a recital, he remarked, provokes the reflection that if one of the old alchemists came to life in our midst *to-day*, after the manner of Rip van Winkle, in all else but technique and terminology he might find himself very much at home. The lecturer then went on to deal with certain developments in present-day practice.]

MATERNAL MORTALITY.

It has been urged, and with truth, that one of the most vitally important branches of medical practice—obstetrics—has not shared in due proportion the benefits accruing from the Listerian epoch with regard to the incidence of infection. Many persons, and many interested bodies, including the Ministry of Health and our Association, have been, in their several spheres, devoting time and earnest attention to the problem, and it is of the first importance that Her Majesty the Queen has personally associated herself with the movement to adequately investigate the governing causes and to endeavour to reduce the maternal mortality and morbidity rates.

No further incentive to this end need be furnished than the oft-quoted facts that more than 3000 mothers lose their lives every year in England and Wales; that in more than half of this number death is due to septic infection which, it is claimed, is, or should be, a preventable condition. Preventable, yes, given certain conditions. It is well known that under properly conducted institutional conditions mortal septic infection arising de novo is reducible to vanishing point. In these establishments the observance of every detail and circumstance of technique designed to secure asepsis can be carried out, and a confidence generated akin to that with which surgery in general is now undertaken.

Inasmuch as, in a country like ours, all cases, or any very considerable proportion of them, cannot be institutionally provided for—the total in England and Wales would require something like 30,000 beds—the problem would appear to be capable of solution if it were possible to reproduce in the homes of the people the essential factors of this provedly effective hospital treatment. This deduction loses little of its force even if it be urged, as with truth it may, that on the one hand there are some rapidly fatal cases of infection in which every known precaution has been taken, and, on the other hand, that some difficult and complicated cases, in the circumstances of which practically no precautions can be observed, may make a smooth recovery. Such cases are the exception and not the rule.

To reproduce, however, in the average home that veritable Temple of Asepsis the operating theatre, with its ministering priests and priestesses, is, of course, impossible. But to be effective the ritual need not be complicated, and the association of antenatal care and, if necessary, treatment; the adequate nursing; the unhurried waiting upon events in suitable cases; and the availability of skilled experience of all kinds if and when required, are equally indispensable elements in the right kind of institutional treatment. There are thousands of general practitioners who, in letter and in spirit and wherever possible, transmute the largest common denominator of these hospital advantages into their practices, and their results attest the fact.

Every practitioner, however, and especially in certain districts, must not rarely encounter such conditions of poverty, ill-housing, previous unskilled interference, and other handicapping circumstances, as render it impossible to practise asepsis, and where accordingly the pathways to infection are hopelessly unguarded. It is gratifying to note that several local authorities are doing much to meet the circumstances of many who cannot afford even a very inexpensive equipment—the maternity benefit notwithstanding—and that the sequel is encouraging.

It is much to be hoped that at no distant date the recommendations submitted by the Association to the Royal Commission on the Insurance Act in regard to this supremely important branch of medical practice will be materialised.

Meanwhile the tendency exhibited in certain quarters to make the general practitioner the scapegoat for the sins of many is to be deprecated. To begin with, he cannot be sent into the wilderness. In his hands, either in the original charge or as a consultant of first instance, must lie the application of the standard obstetrical practice of the day for the great bulk of domiciliary cases. He needs, not blame, but support in the form of the provision of facilities in suitable cases to cope with this most anxious, time-absorbing, underpaid factor of his work. As it is, his devoted response to its calls in most difficult circumstances is worthy of all praise.

There are many aspects of this international problem which are baffling, and one cannot but earnestly hope that the intensified research which is now being directed not only into its bacteriology but also into the question as to the factors which constitute and the conditions which vary resistance to infection, may produce helpful light and leading.

INTERNATIONAL COÖPERATION.

This and many other important topics of international concern are engaging the close attention of the appropriate departments of our annual meeting. Indeed, we are, by the presence with us on this occasion of so many distinguished representatives of other countries and other climes—whom we are delighted to have the privilege of greeting—strikingly reminded of the cosmopolitan character of the science and art of medicine. Orthodox medicine knows no protection barriers and claims no patent rights. The international pooling of ideas, of discoveries, and of experiences is essential to the recognition of even a datum line of the advances in the various departments.

There is an impression abroad—and it is not, perhaps, ill-founded—that in the British Isles we do not sufficiently organise and utilise the wealth of clinical material at our disposal for post-graduate demonstration in the interests of our home profession and of visitors from other countries. Good work has been and is being done in the various metropolitan centres, but these do not claim a monopoly of skill and clinical facilities. I have long felt that, with its wonderfully ramified machinery to link up the provinces and the capital, the rural areas and the towns, no body is so well adapted as our Association to organise a post-graduate system embracing existing institutions and developing many new centres, on a scale worthy of this country.

I am not without hope that there may be forthcoming a national, nay, an international, benefactor willing to entrust the Association, as a voluntary body, with the considerable sum of money necessary to establish and conduct such a system. I am convinced that thus we would not only raise the standard of efficiency, and therefore of health, in this land, but colleagues from overseas and other lands would find it more than ever worth their while to spend some time with us, to our mutual benefit. The advantages would not be limited to our professional spheres, but would surely develop in wider measure social and ethical results of far-reaching significance.

No branch of the League of Nations exerts a wider general influence than the Health Organisation, the head of which, Dr. Rajchman, we are so glad to have with us. That influence is not accidental. It is essential. For may we not, in all humility, venture to claim that no other profession or calling can offer a basis of union so broadly appealing to what is common to mankind as the objective of preventing, alleviating, and curing the diseases of humanity?

A GOVERNMENT HOSPITAL IN LIBERIA.—Mr. King, the President of Liberia, the Negro Republic on the West African coast between Sierra Leone and the French colony on the Ivory Coast, recently opened a Government hospital at Mourovia, the capital. It stands high, is built of stone and concrete, and encircled by wide-covered verandahs. There are 200 beds in small wards and single and double rooms; there are maternity and contagious diseases wards and a pavilion for patients awaiting admission. The hospital is open to patients of any race or colour, and the medical staff is composed of two Europeans and a Liberian, all of whom have been trained in Europe and the United States, and are specialists in tropical diseases. The nurses have been trained in America.

PUBLIC ACTION IN REGARD TO CANCER.*

By Sir GEORGE S. BUCHANAN, C.B., M.D., F.R.C.P. Lond.,
SENIOR MEDICAL OFFICER, MINISTRY OF HEALTH, AND PRESIDENT OF THE CANCER COMMISSION OF THE HEALTH COMMITTEE OF THE LEAGUE OF NATIONS.

We are invited to-day to consider "public action" designed to reduce, in our time, the suffering produced by an ever-threatening disease, to cure it when it can be cured, and, last but not least, to prevent it where knowledge and means are at hand for its prevention. And "public action" for this purpose may be taken to cover every form of collective public effort, whether taken voluntarily, by groups of citizens acting independently of any State medical system, or organised by central or local government authorities out of rates and taxes.

A review of public action, thus conceived, if it were to be just and to take account of the different lines of effort followed in the many countries represented at this Conference, would be a task which is, historically and administratively, far outside my own competence. My best course, I think, will be merely to say a few words as regards this country, and to point to a few of the more recent illustrations which it affords of the benefit which collective action can secure. I will then invite those who come from other lands and work under other conditions of medical practice and public health administration to give us their experience of their own lines of work and help us with support or guidance.

Increasing Recorded Mortality-rate.

For England and Wales, then—from my official limitations I find it easier to deal with this part of the United Kingdom, leaving Scotland and Northern Ireland to their own exponents—I may start by referring to the way in which, in recent years, attention has been directed to the steadily increasing recorded mortality-rate from cancer—a feature which differentiates it from practically all other causes of mortality. It is unnecessary to assume that this recorded increase denotes a corresponding increase in the real incidence of the disease, since it is well known that other factors, such as average increase in longevity, improvement in diagnosis, and improvement in death certification, must all be reflected in the mounting annual figures. Nor will it be forgotten that this over-all increase comprises increases at certain sites of the disease, decreases at others.

But yet consider the following death-rates per million living in England and Wales during the period 1847–1927:—

Certified Deaths per Million from Cancer in England and Wales, 1847–1927.

1847–50 ..	274	1886–90 ..	632	1921 ..	1215
1851–55 ..	306	1891–95 ..	712	1922 .	1229
1856–60 ..	327	1896–1900 ..	800	1923 ..	1267
1861–65 ..	367	1901–05 ..	867	1924 ..	1297
1866–70 ..	403	1906–10 ..	939	1925 ..	1336
1871–75 ..	445	1911–15* ..	1055	1926 ..	1362
1876–80 ..	494	1916–20* ..	1182	1927 ..	1376
1881–85 ..	548	1921–25 ..	1269		

* The mortality for the years 1915–20 relates to civilians only.

Before we write off all this rise as a product of more accurate diagnosis and certification of causes of death, or as due to the steady prolongation of lives into the ages most prone to die of cancer, we must remember the causes which all through this long period have been doing their best, and potently, to produce a fall—vastly improved surgery, anæsthetics, asepsis, new pathology, better medical education, research, and devoted medical work at every stage. Cancer patients have shared with others the benefits of the great developments in the voluntary hospitals, in the poor-law medical service, and in other methods of caring for the sick, which during this time have changed almost beyond recognition. Nevertheless, if all these things have stemmed the tide, the flow continues. It is small wonder, therefore, that in these later and post-war years, when so much attention is being given to the prevention of disease and the reduction of sickness, a desire has arisen in many quarters to see what may be called normal medical effort strengthened by special collective action.

Special Collective Action.

Until lately only a few examples of such special collective action came readily to mind, although they were important ones. There was in particular the foundation of three special cancer hospitals. The primary object of these hospitals, the Cancer Charity of the Middlesex Hospital, founded 1792 (now the Middlesex Cancer Hospital), the Cancer Hospital, established 1851, and the Christie Hospital, Manchester, established 1892, was doubtless that of providing institutional treatment for incurable cases, but each of them has widened its scope, and now treats patients in all stages of the disease, and possesses a modern research department. Then there was the Imperial Cancer Research Laboratory which began with the Cancer Research Fund, now the Imperial Cancer Research Fund, established through private munificence in London in 1902 (under the patronage of H.M. the King) and placed under the direction of the Royal Colleges of Physicians and Surgeons, whose work is known to you all. I should mention also the Radium Institutes in London (1911) and Manchester (1915) which, though also undertaking the treatment of other conditions, are mainly concerned with neoplasia. All the special institutions just mentioned owe their foundation, and in some cases their daily maintenance, to private generosity; they are in no sense State or municipal organisations.

Among the studies of cancer made for the State during the period are, of course, the well-known reports from the Registrar-General's Department, in which the mortality from cancer as a whole and its specified varieties, as judged from certification of causes of death, has been regularly collected and reviewed, annually and decennially, and all the work directly or indirectly bearing on cancer which has depended on the Medical Research Council, and is equally well known to you.

Among instances of State intervention for the control of cancer was the action taken in November, 1919, when by an Order of the Secretary of State for Home Affairs (under Section 73 of the Factory and Workshops Act, 1901), epitheliomatous ulceration due to tar, pitch, bitumen, mineral oil, or any compound, product, or residue of these substances contracted in a factory or workshop was scheduled as a disease the notification of which was obligatory on medical practitioners. In one sense the action was merely part of the normal procedure adopted in the prevention of a disease liable to be caused by occupation, but its value, for a wider purpose, should not be ignored. Lessons learnt in the investigation of cancer caused by occupational risks may have an important bearing upon the elucidation of the nature of cancer in general.

Another step of importance was the handing over to the Medical Research Council, after the war, of a considerable stock of radium in the possession of the Government. This stock has been distributed to selected hospitals and used largely for treatment of cancer, always under the condition that its use is part of research and that the results should be reported to and considered by the Council, with the aid of its Radiology Committee.

Four Recent Directions of Activity.

I come now to certain forms of public action which are of more recent date.

(1) About the end of 1922 the Minister of Health decided to appoint a Departmental Committee "to consider available information with regard to the

---

* Opening a discussion on the subject at the International Cancer Conference on July 20th.

causation, prevalence, and treatment of cancer, and to advise as to the best method of utilising the resources of the Ministry for the study and investigations of these problems." The chairman of the committee is the Chief Medical Officer of the Ministry, and its members include members of the medical profession with expert knowlegde of the disease in its various aspects—experimental, pathological, surgical, medical, statistical, &c.

(2) Following some interesting discussions on the comparative incidence of cancer mortality at the Office International d'Hygiène Publique (October, 1922), the League of Nations Health Committee decided, in 1923, to set up a Cancer Commission, the work of which, so far as the participation of England and Wales is concerned, has since been carried out in close association with the Departmental Committee.

(3) In 1923, also, the British Empire Cancer Campaign was started—a voluntary organisation with its centre in London, the object of which is "to correlate and extend all existing efforts in fighting cancer." The direction of the campaign is in the hands of a body of distinguished men, both lay and medical, and its principal activity, besides the coördinating work, is that of collection and disbursement of funds for promoting research into the causes and cure of cancer.

(4) During the last four or five years some of the larger municipalities have given considerable attention to the subject of cancer, especially those cities which are centres of medical education or well supplied with hospitals. The Departmental Committee above referred to has secured some coördination of this local work by forming a subcommittee, consisting of medical officers of health of the areas in question, which meets from time to time at the Ministry of Health.

(1) DEPARTMENTAL COMMITTEE OF THE MINISTRY OF HEALTH.

I hope to be forgiven for dwelling at disproportionate length on the work done at the Ministry of Health under the guidance of the Departmental Committee, merely because it happens to be well known to me. The standing problem which we then have before us is whether available skill and existing knowledge are, at the present time and with present weapons, being given all the chance to reduce mortality or relieve suffering that they ought to have. For example, does the obstacle lie in the absence of sufficient public propaganda in favour of early diagnosis and treatment, or in the faults of misdirected propaganda, badly conceived and based on half truths? If so, what is good, safe, and effective propaganda? Are cancer patients now presenting themselves for advice, but failing to get it? Is there doubt whether surgery or radiology do produce the results so often claimed for them, and how far is that doubt justified by the facts? Is the main difficulty one of getting sufficient facilities for early surgical or radiological treatment; are there, in fact, long waiting-lists of patients; and what should be done about it? Do we know enough of the conditions of incurable and inoperable cases, and are they alleviated as much as they could be? Finally, is there anything useful to be said as regards the way in which conditions which lead to cancer can be avoided? What do we really know about such conditions; are they as a practical matter avoidable; and if so, in what way?

Now the information needed to resolve these questions is not of the type which can usually be obtained by cancer research workers, whether in laboratories or the wards of hospitals. It demands the laborious collection and scientific statistical analysis of massed data regarding the conditions associated with the onset of cancer, the effects of various methods of treatment, and many other investigations for which it is almost essential that the resources of the central health authority should be added to those of other investigators. Work in these directions, moreover, requires that national experience as a whole should be checked and compared at different stages with that of particular local areas on the one hand and with that of different countries on the other. The Departmental Committee has endeavoured to secure both by the liaison systems I have mentioned, through its Medical Officer of Health Subcommittee, and through its representation on the League of Nations Cancer Commission respectively.

Data for Cancer of the Breast and Surgical Results.

The work alluded to has so far been chiefly concerned with the disease at the three sites—breast, uterus, and rectum. In the case of cancer of the breast a statistical analysis undertaken of published literature and of the clinical records of hospitals established on a broad basis the fact that operative treatment (by which is to be understood the complete operation) results in the survival for long periods—ten years—of as many as 80–90 per cent. of patients if they submit to operation at an early stage of the disease—i.e., before it has spread beyond the confines of the breast. Once the disease has spread beyond the breast the chance of prolonged survival diminishes rapidly. In both categories the analysis made did more than confirm an opinion long held by surgeons; it brought the facts into terms capable of precise expression and established a firm basis on which the medical profession and the public are safe in acting. There is, moreover, no escape from the practical conclusion; without any extension or alteration of existing facilities for diagnosis or treatment a very large number of the lives now lost from this cause could be saved if a larger proportion of patients were submitted to operation in an early stage of the disease. Using data which permitted lessons to be drawn from average figures, it was found that an average interval of some nine months is allowed to elapse between the patient noticing the abnormal condition and seeking treatment. While it is not possible to state an average period necessary for spread of the disease to the axillary glands, in a large proportion of patients these glands are affected within six or seven months of the onset, as observed by the patient.

It is not too much to say that this demonstration that early operation affects such an overwhelming proportion of cures (for absence of recurrence after ten years can usually be regarded as a cure) surprised many surgeons. The figures seemed too good as an index of the average results obtained by surgeons in general. But the conclusions of the Committee have been strengthened by a later analysis of a still larger sample of English hospital cases in a report not yet published. In this later analysis the results after operation were also correlated with the microscopical characters of the growth. Though there was evidence that the glandular and colloid varieties had a higher survival rate than the spheroidal-celled growths there was no evidence in the latter that the more cellular growths had a worse prognosis. It was also found, contrary to the general impression, that risks of recurrence are not appreciably greater in younger than in older patients. In all cases the most important factor in prolonged survival is the stage of the disease at which appropriate treatment is applied. And in all cases the hopeful method, at present, of reducing mortality is to find some means of inducing women with an abnormal condition of the breast to seek treatment as soon as any abnormality manifests itself.

The analysis has also enabled the factors which have been thought to be of importance as predisposing causes to be sorted out and their influence statistically assessed—*e.g.*, infertility, injury, chronic mastitis, and transient non-suppurative mastitis—matters in which it has now proved that the experience of certain foreign countries is closely parallel to that of England.

"Natural Duration."

The Committee at an early stage found that they needed another piece of knowledge—namely, the average interval between the onset of the disease, as observed by the patient, and the fatal termination in those cases where for one reason or another no attempt at radical treatment had been made—i.e., an average figure representing the so-called "natural duration" of the disease.

Earlier observations had shown that "natural duration" varied considerably with the organ affected. It had long been recognised that, especially in the breast, the course of the untreated disease might be extremely protracted, occasionally to 20 years or more, and it was also known that some cases ran an unusually rapid course. But the large series of observations collected for the Committee have enabled a useful series of average "natural durations" to be estimated on a large numerical basis. For some of the commonest accessible sites they are as follows:—

Breast..	38 months.	Tongue and mouth	16 months.
Uterus..	20 "	Larynx..	14 "
Rectum	26 "	Œsophagus	12 "

Data for Cancer of the Uterus; Alternatives to Surgical Treatment.

Turning now to the site next investigated—the uterus—it may be said briefly that much the same principal deduction from the public health standpoint emerged—viz., that the earlier the disease was surgically treated the better was the result. Moreover, similar conditions prevailed in respect of delay in seeking treatment, the average interval in this case being somewhat shorter than in the case of the breast. This presumably is to be correlated with the shorter natural duration.

But for cancer of the cervix uteri an entirely different factor came into the field of investigation—viz., the alternative method of treatment by radiology—necessitating a comparison of its results with those of surgery. Broadly it appeared that in operable cases the percentage of survivals to five years might be approximately the same for both kinds of treatment—viz., 40. Additionally, of those patients who were beyond the reach of surgery some 10–12 per cent. were freed of their disease for the same period by radiological methods. When it is remembered further that these results of radiology are obtained at practically no immediate risk of death and that in more advanced cases still, where eradication of the disease seems out of the question, considerable alleviation of symptoms can be secured, it becomes clear that at this site we have a method of treatment equal if not superior to surgery.

From the public health standpoint another aspect should be mentioned. It seems probable that, with wider use of a method of treatment less repugnant to most women than operation, one of the probable reasons for delay in seeking treatment may be eliminated and opportunities for securing a larger proportion of survivals improved.

If this attitude towards the treatment of cancer of the cervix is broadly true it gives a different orientation to the subject and brings it much more closely into the sphere of "public action." One has only to consider the cost and special nature of radium, the complexity and delicacy of deep X ray apparatus, and the specialised skill needed for its application. A greater degree of organised centralisation for radiological treatment becomes inevitable if radiological treatment is to effect the great benefit and life saving which it can apparently produce.

Data for Cancer of the Rectum.

With the aid of the Departmental Committee the Ministry of Health has also undertaken an investigation of the literature relating to the surgical treatment of rectal cancer. This proved more difficult and in some ways less conclusive than those into cancer of the breast. The operative treatment was more recent and less standardised, a greater number of variable factors to be taken into consideration, while in this case there is greater difficulty of diagnosis and greater inaccessibility of the growth. Though the operative mortality was high (about 16 per cent.) the proportion of survivals to three years amounted to nearly 40 per cent. Here also the average delay between the onset of symptoms and seeking treatment was serious, extending to 13 months—an important reason for the rarity with which these cases could be regarded as operable.

Relationship of Cancer to Dietary.

A subject which has given rise to much theorising is the possible relationship of dietary to cancer. The line of thought commonly followed is that as native races, whose diet is more "natural" than that of white races, suffer from cancer to a less degree than others, the two events are probably correlated. Whether it is true that native races are less affected is really not yet known; much has been said on the subject, but the data needed for judgment do not exist. But supposing it to be the case, it does not follow that the native immunity is to be explained by the existence of a causal relationship between diet and cancer. The Departmental Committee in this connexion was fortunate enough to have a good opportunity for inquiring whether cancer mortality was low in members of religious orders subjected to certain dietetic restrictions. A somewhat detailed investigation failed to adduce evidence in support of the contention.

Reports and Further Programme.

The technical reports in which the foregoing deductions were drawn have been issued among the series of Ministry of Health reports on Public Health and Medical Subjects, published by H.M. Stationery Office.[1] In addition they have been made the basis of non-technical memoranda[2] issued by the Ministry of Health for the information of local health authorities and the general public.

This kind of work at the Ministry of Health is continuing—it is extending to radium treatment, cancer of the skin and lip, and other matters. It is an attempt at thorough stock-taking of the position in one section after another, intended to be useful not only to the Government departments and to local health authorities, but to practising physicians and surgeons and to the public. It will also be of value, I hope, for reference in future years; we would give much to be able to assess our progress by reference to similar comprehensive studies if they had been made, say, 30 years ago.

(2) CANCER COMMISSION OF THE LEAGUE OF NATIONS.

For appreciation of the inquiries into cancer which the Health Committee of the League of Nations decided to regard as appropriate to its functions, I may commend to your notice the summarising report (C.H. 631, 1927) made recently by the Cancer Commission, which covers the work done, with the aid of its statistical subcommittee and other experts, from 1923–27. They originated in an attempt to account for the remarkable differences in mortality at two sites, the breast and uterus, as shown in the national statistics of three countries, England and Wales, the Netherlands, and Italy. For example, the death-rate for cancer of the breast in the Netherlands is little over one-half of that shown by the English figures, and the rate in Italy is about one-half that of the Netherlands. As regards the uterus, the rates for Italy and the Netherlands are approximately the same, being somewhat higher in the former; but both are considerably lower than the English rate. Such differences are frequently to be found in different parts of the same country, but in this case the national contrasts were strong and their investigation seemed promising. Prolonged and exhaustive inquiries from the statistical, clinical, and other aspects were made into a whole series of factors which might be thought to have produced these effects. Many plausible and conjectural explanations were taken up, but one by one were shown to be of no validity. But while the explanation of these national differences remains still hidden, and the Commission concluded that it is useless to seek further for it, the investigations which were put in hand led to useful results in other directions. A particularly interesting by-product was an anthropological distribution of races in Europe, worked out by Pittard and Niceforo, with which known facts as to cancer mortality were correlated. Much work similar to that of the English Departmental Committee was undertaken by national groups of experts, not only in Holland and Italy, but also in other countries. This settled various questions on the basis of the experience of several countries; for example, it determined the statistical relations between fertility and cancer of the breast; it confirmed the dictum that the essential point in the relation of cancer of the uterus to parturition is the fact of parturition and not the number of pregnancies, while in regard to the success of early operations the foreign statistics were closely parallel to that obtained by the English group. The Commission insisted on practical lessons derivable from its inquiries, notably as to the need for greater resort to surgery or radiology at appropriate stages, the importance of attention to obstetric methods to prevent the occurrence of chronic inflammation of the cervix, and the advantages of greater national and local expert coöperation for research into cancer problems. They considered also that their inquiries had shown that there is urgent need, in all countries possessing an organised official service of statistics of causes of death, to determine more exactly the degree to which certification by causes is unsatisfactory and how its scientific value may be improved. In the case of cancer such inquiries should take account of the need for uniformly attributing cancer deaths to the primary site of occurrence.

Stationery Office, Kingsway.

Following this report, the Health Committee at Geneva laid down, last May, certain other lines of inquiry for its Cancer Commission, which seemed to require the kind of expert liaison which the League is in position to supply. Among these are the different incidence of cancer associated with the same occupation in different countries, and the results of radiological treatment of cancer. A subcommission of expert radiologists and gynæcologists under the presidency of Prof. Regaud began its work last month on the *latter subject*.

(3) THE BRITISH EMPIRE CANCER CAMPAIGN.

Imbued with the necessity of increasing the volume of investigation devoted to the various means for controlling the disease, a body of public-spirited men undertook to form an organisation whose main object was, by financial assistance, to coördinate research, extend existing research centres, and to stimulate the formation of new ones. The funds subscribed to the headquarters of the Campaign in London are allocated to individuals or centres who desire to carry out investigations into any aspect of the cancer problem which is considered likely to be of value, whether direct or indirect. The annual reports of the Campaign set out the allocations made and the purposes to which they were put.

Apart from the central organisation, provincial ones have been initiated, among which may be mentioned the Yorkshire Council, which has collected a large sum of money and set up an active research centre in association with the University of Leeds. Similarly, another organisation, to embrace Lancashire, Cheshire, and North Wales, seems likely to succeed in extending the existing facilities for research in the University centres of Liverpool and Manchester. Somewhat similar efforts, varying with local circumstances and conditions, have been set up in other county areas and university towns.

Another type of action taken by the Campaign is the publication of the *Cancer Review*, a journal devoted to improving the means by which English readers may become more readily acquainted with the work proceeding elsewhere both at home and abroad. There can be no doubt of the value which this journal already possesses for those interested in any of the scientific aspects of cancer research.

(4) MUNICIPAL WORK.

Under this head it is well to draw attention to what is done in several important provincial centres to utilise the public health department, working through the medical officer of health, as a centre for the local study of the disease and for other practical effort in various directions. The work of several health departments, particularly those whose medical officers of health are included in the special subcommittee which meets at the Ministry of Health, has been invaluable to the inquiries which have been required for its Departmental Committee. Much of the information which has been needed in regard to the conditions associated with cancer, and those which require "follow-up" work, has been obtained by the medical or trained health visitor staff of these provincial centres. The local data have been valuable too for essentially local purposes; the health department has obtained present-day standards by which to measure progress in later years, while the local inquiries have brought out deficiencies which can be rectified in the matter of hospital and home treatment, and have permitted useful experiment. Thus in one or two centres trial is being made of special centres or clinics for women to facilitate early diagnosis of cancer of the breast and uterus. At others different methods of propaganda and educative action are adopted for the same purpose—lectures, talks, leaflets, and the like. The principle to be followed throughout all this local work is to secure the closest possible common action between the municipal health department and the authorities of the general and poor-law hospitals, the university if there is one, the voluntary agencies which support social work, and especially the staffs of hospitals and the medical practitioners—e.g., through the local branch of the British Medical Association—as well as the local work of the British Empire Cancer Campaign, where it is in operation. It is no part of the programme that municipal direction should be made prominent; it is enough for the health department if it can help. Where the medical officer of health is wanted to take the initiative he will do so, otherwise he is content to be one of many cogs on a useful working wheel. Personally I may express the opinion that cancer research has much to gain through his instrumentality, and the experience we already have is my justification.

In reviewing this brief outline of public action in England, and its recent developments, one is conscious of its patchwork, incompleteness, and even its inconsistencies and overlaps. Compared with some extensive efforts in the United States of which I have read, with the *centres anticancereux* throughout France, or with a State cancer institution such as is represented by the new Institut Victor Emmanuel III. in Milan, it may seem meagre. But at least it has in it the elements of elasticity and capacity for development on almost every side, whether in pathology, causation, diagnosis, or treatment, as occasion requires.

VICTORIA HOSPITAL FOR SICK CHILDREN, HULL.—Last week the Right. Hon. T. R. Ferens opened a new ward and named it "The G. F. Grant Ward," in compliment to the treasurer, who has been associated with the institution for 40 years. The two rooms which compose the new ward will be used for ophthalmic, and nose, ear and throat cases respectively.

CHEMOTHERAPY IN MALIGNANT DISEASE,

WITH SPECIAL REFERENCE TO LEAD.*

BY W. BLAIR BELL, B.S., M.D. LOND.,
HON. F.A.C.S.,
PROFESSOR OF GYNÆCOLOGY AND OBSTETRICS IN THE UNIVERSITY OF LIVERPOOL.

IN the few minutes at my disposal in which to open this discussion, I can do little more than briefly outline the scientific basis, the scope, and what may be the future developments of so-called "chemotherapy," especially lead-therapy, in the treatment of malignant neoplasia. First, however, it is necessary to decide what is meant by the word "chemotherapy." "Chemotherapy" probably dates from that remote period in the history of mankind when the treatment of disease was first recognised as being possible. But, as a science, "chemotherapy" came into existence in the last half of the nineteenth century following the bacteriological discoveries of Pasteur and the synthetic enterprises of Ehrlich. It is, however, somewhat unfortunate that the word "chemotherapy," which has a very general meaning, should have been adopted for use in the somewhat restricted sense in which it is usually employed to-day.

Definition of the Word "Chemotherapy."

"Chemotherapy" is defined in Dorland's Medical Dictionary as "Treatment based on the selective affinity which various chemicals have for the tissues of the body and for the organisms that may infect it." Kolmer[1] states that "The term chemotherapy is difficult to define in a brief and concise manner," and he calls attention to the chemotherapeutical affinity shown by drugs like strychnine, digitalis, morphine, cinchona and the rest. It seems, therefore, that we are in need either of a less general term to describe the chemical methods applied to the treatment of parasitic and neoplastic diseases, or of a limitation of its meaning. "Chemotherapy" has become so incorporated in our medical vocabulary that limitation of its application would probably be the better procedure, and I would suggest the following definition. *Chemotherapy denotes treatment by synthetic preparations which have a selective therapeutical action on abnormal tissues of the body and on the organisms that may infect it, with or without the production of associated constitutional phenomena.*

Chemotherapy Applied to Malignant Disease.

Selective chemical treatment in respect of malignant neoplasia may be based on a belief in some supposed causal factor, such as a parasite. Doubtless in these circumstances the therapeutist would seek to develop along the recognised lines the known synthetic parasiticides, none of which is unispecific—that is, specific for one organism only.

Those of us who do not favour the idea of the existence of a specific parasite in connexion with cancer, but believe rather that malignant neoplasia is a specific growth-process (dedifferentiation)—a process that is initiated by many predisposing factors—will turn first to the quest of the mysterious agent or agents that normally control differentiation and somatic correlation. I have not time, nor would it be pertinent to a discussion on chemotherapy, as defined, to dwell on the many observations that have been made in respect of these phenomena, especially by means of experiments in vitro.

Failing to discover the biological—that is, natural biochemical—regulators of differentiation, we must seek some chemical substance that will arrest growth as such, and endeavour to discover one that has also an inhibitory action on the essential functions of the cancer cell, or a selective affinity for some part of its chemical constitution, and some influence on its physicochemical state. In order to produce its effect it should be possible for the chemotherapeutical agent to be injected into the blood stream, and it must reach the cancer cells. Further, in accordance with the principles of chemotherapy, the preparation should have as high a chemotherapeutic index as possible.

If our chemotherapeutical methods are successful we shall expect to find: (*a*) destruction of the neoplastic cells—necrosis; or (*b*) arrest of the growth: (1) without complete disappearance, (2) with gradual disappearance; and we might add a third event, although it is improbable—namely, the redifferentiation of malignant into normal somatic tissue.

If the growth be of large size and undergo rapid necrosis, it is hardly possible that the normal tissues of the host will deal with the necrosed tissue without surgical aid; but when the neoplastic cells are seriously damaged and their devitalisation is gradual, the normal tissue reactions may be such as to lead to the removal of the dead or dying cells. This, apparently, is what happens in successful treatment by X rays and radium.

Lead-therapy in Malignant Disease.

In order to make clear the rationale of the treatment of malignant disease with lead, I must digress first to explain our views on the nature of malignant disease, and, secondly, to illustrate the properties of lead that are concerned in the chemotherapeutic action that may occur.

I have spoken of the specific growth-process of dedifferentiation. It is impossible here to discuss the views that have been advanced on this subject. It is, however, a process that hardly admits of dispute at the present time. The essential point, so far as our own views are concerned, is that this reversionary process is directed towards the trophoblastic type, perhaps through, rather than to, that of the embryonic somatic anlage. Hence the adult somatic cell that undergoes dedifferentiation passes back through the later stages of somatic development before reaching the primitive type. Consequently malignant neoplasms vary considerably in the degree of dedifferentiation that they have undergone, and the most malignant tumours are those in which dedifferentiation is greatest.

In very malignant tumours we should, therefore, expect to find syncytium, as indeed we do. Furthermore, it may reasonably be held, as I have previously suggested, that those forms of so-called "chorion-epithelioma" that are unrelated to pregnancy, for example, "chorion-epithelioma" of the testis, represent merely a high degree of dedifferentiation, and, therefore, of malignancy. A large part of our work has, then, been directed to the demonstration of the chemicoconstitutional and functional—and not only to the morphological—resemblances between the chorionic epithelium and malignant cells of somatic origin.

Now, it seems that every chemotherapeutical agent employed in malignant neoplastic disease should have two attributes at least: (1) the power to arrest cell-growth generally; (2) a special affinity for malignant cells and the chorionic epithelium.

It has long been known that lead arrests growth generally and causes abortion in the human subject. We have repeatedly shown experimentally that the growth of plants and animals is very definitely checked by this substance. We have also demonstrated that lead in suitable doses causes coagulation necrosis of the chorionic epithelium and that abortion is the result of this, rather than a sequel to intrauterine hæmorrhage of toxic causation. The chemotherapeutical index of this effect by a pure lead colloid is approximately 2—a very low ratio. Moreover, we and others have obtained experimental and clinical evidence that lead may cause a similar necrosis of cancer cells in favourable circumstances, but again the chemotherapeutical index is very low.

---

* Opening a discussion on the subject at the International Cancer Conference on July 19th.

[1] Kolmer, J. A.: The Principles and Practice of Chemotherapy, with special reference to the Specific and General Treatment of Syphilis, 1928.

Lead in Tumours.

We have found that after treatment lead may be recovered from malignant neoplasms in considerable quantity. In two human cases the lead-content of the malignant tumour definitely exceeded that of the neighbouring normal tissue.

In the case of a carcinoma of the liver, secondary to carcinoma mammæ, the tumour held 41 parts per million of lead, and the adjacent hepatic tissue 11 parts per million. This is an important observation, for lead is always present in large quantity in the liver after the intravenous administration of this metal.

In the other case, a periosteal sarcoma, the tumour contained 12 parts per million of lead, whereas the normal bone in the neighbourhood contained 1 part per million.

Waterman, likewise, has made interesting observations in regard to the lead-content of the primary tumour and pulmonary metastases in chicken sarcoma. His finding that the pulmonary metastases contained more lead than the primary growth may, perhaps, be explained on the ground of the vascularity of the lungs. Waterman has also shown that tumours treated with lead in vivo are not so readily transplantable as untreated neoplasms.

The Mechanism of the Action of Lead.

Although much work has been done by my colleagues, Prof. W. C. McC. Lewis and his associates, with a view to discovering in what way lead acts on normal growing tissues and on malignant cells, no very definite conclusions have, as yet, been reached; but it appears possible that the action in regard to cancer is both local and constitutional. In respect of the latter some observations on the restoration by lead of the lipase co-enzymic activity in the serum of cancer patients have recently been published by these members of the staff of the Liverpool Medical Research Organisation. It may be remarked, however, that the local effects are likely in the long run to be of much greater significance than the constitutional.

The position at present, then, is that lead inhibits growth and affects the cancer cell deleteriously. Whether this selective action is associated with growth processes only, or in addition, as we think probable, with some special function or constitution of the cancer cell, remains to be finally proved; the question has, however, an important bearing on the chemotherapeutical aspect of the subject.

Apart from this there is another matter that has exercised our minds, and it is this. Since, from whatsoever angle we regard dedifferentiation, we must come to the conclusion that cancer cells resemble in many ways morphologically and functionally the cells from which they are derived; and it follows that the less dedifferentiated the cells are the more they will resemble those from which they arise. For illustration we may mention cancer of the thyroid and cancer of the liver.

It seems, therefore, that in the synthetic preparation of any chemotherapeutical substance, such as a lead-complex, we should take into account not only the specific action of the remedial agent in regard to growth and the malignant cell generally, but also, so far as our knowledge permits, we must consider the special chemical constitution, function, or evokable reactions of the differentiated (specialised) tissue in which the malignant neoplasm has developed. For example, it may be suggested that a sulphur-lead complex should be specially useful in cancer of the skin. One can envisage that the ideal combination would be one in which the affinity of the lead for the sulphur was such that the combination would only be broken by the cancer cell, without previous alteration of the lead-complex.

This method is, of course, simply a way of making the poison more acceptable to the cancer cell, and of enabling it to reach its objective, and so produce the maximum effect.

If it were found possible to make on these lines a preparation of lead which was absolutely specific for any one well-defined type of malignant growth, it would appear that the lead preparation used should vary according to the original tissue from which the neoplasm has sprung.

The Present Position of Lead-therapy.

On such an occasion as this, and in the presence of so many distinguished investigators in the difficult field of cancer research, all of whom know that patience is required in the final solution of this problem, I have felt it wise to confine my remarks meticulously to the title assigned to the discussion and to the time allotted to me.

I have said enough to show that even though we have reached the stage of believing that lead is detrimental to the cancer cell, just as arsenic was long known to be to the spirochæte, we have still far to go; consequently, an analysis of our clinical results, however interesting, would be informative only in respect of the beneficial effects observed, and I have on several previous occasions adduced evidence on this point.

If there is to be discussion of the continually changing position in respect of clinical treatment, I would indicate, if I may be permitted to do so, the lines along which such discussion may, perhaps, most profitably proceed: (1) the preparation of lead employed; (2) the methods of administration: (3) the effects on cancer of the administration of lead followed by exposure to radium; (4) the same followed by exposure to X rays; (5) the effects on cancer of operation, including diathermy, followed by (or preceded and followed by) the administration of lead; (6) the effects on cancer of the administration of lead alone; (7) the effects of lead on other hyperplastic and neoplastic diseases, such as lymphatic leukæmia and lymphadenoma.

I anticipate that the consensus of opinion will bear out the statement I made in the first paper published on this subject (1922) that the effects of radiations are augmented by the previous use of lead. Also, the employment of lead as a prophylactic measure against recurrence after surgical operations for cancer, will, I think, be held to be of great value. Last, but not least, there is a considerable body of evidence supporting the view that by itself lead, even in the crude preparations now used, can cause the disappearance and apparent cure of malignant neoplasms in favourable circumstances, and sometimes can beneficially affect leukæmia and other neoplastic conditions.

Evidence that may be adduced to controvert these statements must be analysed in regard to the modes of procedure practised, and the nature of the cases to which the treatment was applied.

In conclusion, I would repeat that which I have attempted to indicate in my remarks, namely, that the problem of successful chemotherapy in malignant disease, on the basis of the definition I have submitted, is one of extraordinary complexity, but that it is one which is worthy of careful investigation and exploitation.

NORFOLK AND NORWICH HOSPITAL.—After holding for 37 years the post of honorary physician to the Norfolk and Norwich Hospital, Dr. F. W. Burton-Fanning has resigned. In their resolution of appreciation of his services the Governors congratulate him on researches which have increased the sum of general medical knowledge and enhanced the reputation of the hospital.

WAKEFIELD CLAYTON HOSPITAL.—Last week Mr. G. C. Childs, of Camden, New Jersey, a Wakefield man, who has made a fortune in America, opened a new out-patients' wing which he has provided at a cost of £30,000. The accommodation includes departments for the ear, eye, and throat, massage, ultra-violet rays, dental surgery, medical and surgical consulting rooms, casualty rooms, an operating theatre, and a dispensary. Mr. Childs has promised, in addition, to provide a new ward.

TWO CASES OF "CONTRACTION RING."

WITH OBSERVATIONS ON TREATMENT, ESPECIALLY BY AMYL NITRITE.

By C. R. CROFT, B.M., B.Ch. Oxf.,
LATE OBSTETRIC HOUSE PHYSICIAN, ST. THOMAS'S HOSPITAL.

THE first account of a case of "contraction ring" is by Smellie,[1] who in 1743 visited in a workhouse a woman who had been in labour five days and "neglected by the surgeon and midwife of the house." He found that the head was low in the pelvis and tried to deliver her with forceps, "but," he adds, "was surprised that I did not succeed when I found the head was not large, the instrument so easily introduced and firmly fixed." He performed craniotomy, and fastened a hook in the skull, but could not, with all his strength, bring it along. After removing the skull bones he "found the under part of the uterus strongly girt or contracted round the neck of the fœtus." "This I gradually dilated, bringing down one of the arms, and pulling on that and the shattered bones and scalp with both my hands, I at last extracted the child with greater ease than I expected. . . . In pushing up my hand to dilate, my fingers passed the mouth of the womb that was girt round the middle of the head, when I was surprised to find another contraction before the shoulders." The puerperium in this case was prolonged.

The next case is that of Baltzell,[2] who describes early rupture of the membranes and a long labour in an extremely fat and corpulent primigravida. After several attempts at delivery the final treatment adopted was "abstraction of blood by copious venesection to relax the system and to embrace the moment of its immediate effect to extract the fœtus with the forceps." This also failed, and the patient expired after 70 hours. Four hours after death a post-mortem examination was made, and it was found that "near the neck and shoulders of the child, the uterus had the appearance as if a circular band about half an inch wide had been forcibly drawn round it."

In 1870[3] Gay described a case of obstructed labour in which the bony pelvis was normal, and with some difficulty he managed to get his hand above a ring of contraction in the uterine wall. Here his hand was "trapped," and, being unable to withdraw it, he proceeded to make a more complete study of the condition, which was typical of what we now know as "contraction ring." In 1882 Smith[4] published the "first work on the question" (Chéron). This consists of a weighing of the evidence for and against Bandl's hypothesis of the formation of a new cervix in the later months of pregnancy from the lower segment of the uterus, upper part of the vagina, and cervix uteri. This idea had already been sharply criticised four years previously by McDonald[6] of Edinburgh, who maintained that Bandl's ring was "conspicuous only by its absence." Smith's own contribution to the matter was a collection of 30 cases of "hour-glass contraction," from which he excludes all "doubtful cases, such as rigid os." He makes no mention nor distinction of the condition now known as "tonic contraction." In 33 labours of 30 women, 8 mothers and 25 children were lost. Three women died undelivered, and, as only seven of the women were primiparous, the remainder had presumably had previous successful pregnancies; this would largely exclude from his series tonic contraction due to mechanical obstruction. He points out that the most general symptom present in these cases is early discharge of liquor amnii. Seven children were saved by turning, and one child by forceps. "The craniotomy record is sickening"—ten cases. He discusses the possibility of Cæsarean section, but finally sums up against it.

Chéron's exhaustive treatise of 1899[7] describes 59 cases; the author had personal knowledge of 18. He makes no distinction between "hour-glass contraction" and the retraction of obstructed labour. In fact, he makes the following statement: "La rétraction isolée de l'anneau de Bandl est un phénomène qui n'est point démontré par les faits cliniques; il est toujours accompagné par la rétraction du corps utérin." Of the cases described, many are clearly associated with pelvic contraction, and his summary of the causes of the condition shows confusion between the two main types recognised at the present time. Among maternal causes he gives obstruction to the passage of the fœtus, early rupture of the membranes, prolonged labour, the premature use of ergot, and in particular the use of bags. Of fœtal causes he states that the most common are shoulder, incomplete breech, and face presentation. The paper is largely concerned with the comparative difficulty and danger of embryotomy and version.

Herman,[8] in 1902, doubted the existence of contraction ring.

Clifford White,[9] in 1913, drew a distinction between contraction ring and retraction ring. In reviewing the treatment to be adopted in contraction ring he first observes that expectant measures are useless, and quotes cases in which they had failed. He mentions the drugs in common use at the present time—i.e., chloroform and morphia—and also two cases successfully treated by amyl nitrite. None of these drugs does he regard as of material value. In his series of 90 cases he finds that where no laparotomy took place the maternal mortality was 58 per cent. and the fœtal mortality 63 per cent. In those in which laparotomy was performed the maternal mortality was 31·5 per cent. and the fœtal mortality 42 per cent. He mentions Willett's[10] method of continuous weight-traction, first employed in 1912, in which a weight of 8 lb., representing a pull of 6¼ lb., brought about delivery after three hours. Williamson, by gentle traction with forceps for 15 minutes, had similar success, marred only by incomplete rupture of the uterus. A third case of contraction ring causing obstruction to the delivery of the after-coming head and overcome by gentle traction was described at the same time.

Author's First Case.

CASE 1 was a primigravida of 27, due to be delivered on Nov. 6th, 1927. She had a bony frame of large proportions, and was grossly obese, so that accurate examination was impossible. Her medical history was stainless, beyond the fact that since puberty she had become extremely fat and heavy. She said that her weight was 17–18 stone. Labour pains began at 1 A.M. on Oct. 20th, and became slowly more severe and frequent up to 3 A.M. on Oct. 21st, the membranes having ruptured shortly before that hour. Her doctor was sent for, and, finding the os fully dilated, attempted to deliver her with forceps. In this he was unsuccessful, and, summoning further assistance, he examined her under chloroform, found that the occiput was posterior, and again failed to deliver her.

On admission to hospital her pains were moderate in severity, her temperature 98·4° F., pulse 96, and lacerations were present at the vulva. The uterus could barely be made out; the presentation could not be determined, and the fœtal heart could not be heard; this was not surprising in view of the thickness of the abdominal wall. Vaginal examination without an anæsthetic was impossible, owing partly to tenderness of the lacerations and partly to the fat surrounding the vulva. At 10.45 A.M. an anæsthetic was given, and examination showed that the os was fully dilated. The vertex was only moderately low and had not reached the pelvic floor. It lay well in the brim, and it seemed clear that the pelvis was causing no obstruction to the passage of the head. The occiput lay posteriorly. Attempts at rotation were fruitless, and no rotation could be achieved even when the vertex was with difficulty pushed just above the pelvic brim. The diagonal conjugate was 4 inches. It was not possible to get the hand above the head, but this was thought to be due to general mechanical difficulties of examination, and no further cause was sought. Finding no obstruction to the descent of the head, the forceps were applied, but soon abandoned when even strenuous efforts failed to cause any descent.

Examination by Dr. J. P. Hedley an hour later revealed a non-pulsating cord around the child's neck, and above this a rigid band of uterine muscle closely surrounding the neck. The lower border of this band lay just above the level of the pelvic brim. The skull was perforated, the bones of the vertex removed, and a cephalotribe fixed to the base ventricular node and bundle) is seen to form seven distinct connexions. These are: (*a*) Through its branch to the atrial septum with a posterior atrial vessel, a descending branch of the ramus ostii cavæ superioris, and anterior atrial branches from the right and left coronaries. (*b*) In the interventricular septum with branches from the right and left coronaries, and a branch arising from the right coronary near its origin. Of this last vessel, which occurs in 20 per cent. of my series, I can find no previous mention. Its importance, moreover, merits a fuller description. Leaving the under surface of the right coronary close to its origin, it runs downwards and backwards in the substance of the crista supraventricularis to reach the interventricular septum, where it anastomoses with the septal branches of the anterior descending division of the left coronary (Fig. 3) and, in some instances, with the ramus septi fibrosi. This artery was present in five hearts showing extensive disease of the proximal portion of the anterior descending branch of the left coronary. It may assist in supplying the right limb of the bundle.

Stress is laid on this anastomotic network supplying the neuromuscular tissue because of its importance in the interpretation of clinical findings. Injury to the conducting tissue (heart-block, bundle lesion) is shown on electrocardiographic tracings. Tracings in cases of coronary occlusion show these rarely; in some they are transient,[2] the ordinary blood-supply being apparently able to protect this important tissue. Géraudel[3] reports two cases of Stokes-Adams syndrome in which the ramus septi fibrosi (artery to the node and bundle) was stenosed. My present series includes a case in which partial occlusion of this vessel did not produce a lesion recognisable by the electrocardiograph. This heart showed a well-developed atrial branch of the ramus septi fibrosi communicating with the anastomotic network in the atrial septum.

The attention that is being focused at present on the clinical diagnosis of coronary thrombosis adds interest to some of my cases. I shall pass over them briefly here as a more detailed survey of the series is in course of preparation.

It was observed that an early sign of coronary disease was a narrowing of the lumen of the small twigs of the coronary vessels. This gave these small vessels an appearance of having been nipped just at the point of leaving the parent vessel. Numbers of hearts were found with partial or total occlusion of a coronary artery or its branches. Five of these presented a large area of infarction, others fibrous plaques in the myocardium, while others showed no lesion apparent to the naked eye. These hearts without exception had highly developed compensating anastomotic channels, a beautiful subendocardial network in a case of gross infarction being sufficiently rich to preserve the lining layer of the organ. Two specimens of complete right coronary occlusion are of especial interest. Röntyum injected into these via the patent left coronary artery was found to have filled the occluded right coronary. This occurred through connecting channels chiefly in the interventricular septum.

FIG. 3.

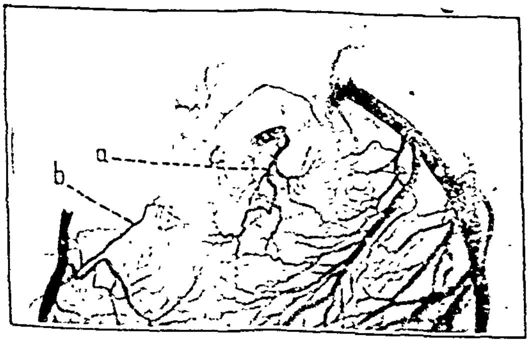

Diagram of upper portion of interventricular septum. (*a*) Artery present in 20 per cent. of cases (additional supply to right limb of A-V bundle). (*b*) Ramus septi fibrosi.

This article refers to the first 92 hearts in my series.

My best thanks are due to the honorary staff of the Royal Victoria Hospital for the material put at my disposal; and to Mr. Leman and Miss Baird, of the radiological department, for their technical assistance.

Clinical and Laboratory Notes.

SERUM PROPHYLAXIS IN MEASLES.

BY D. SAGE SUTHERLAND, M.D. GLASG.,
MEDICAL SUPERINTENDENT, MONSALL HOSPITAL, MANCHESTER; CLINICAL LECTURER IN INFECTIOUS DISEASES, VICTORIA UNIVERSITY OF MANCHESTER;
AND
J. S. ANDERSON, M.D. ABERD.,
SENIOR ASSISTANT MEDICAL OFFICER, MONSALL HOSPITAL, MANCHESTER.

IN recent years attention has been more and more directed to the study of measles, and while an advance has been made in the provision of increased hospital accommodation for the treatment of the disease, the preventive aspect has not received its due recognition. It is 12 years since Nicolle and Conseil, in France, and Park and Zingher, in America, first published the results of their work in this direction, and since then comparatively little additional literature has appeared on the subject. This paper is based on work at Monsall Hospital, Manchester, the opportunity for which was furnished by an epidemic of measles of considerable proportions in that city during the last few months of 1927.

It is well known that the serum of patients convalescent from measles can be used either to prevent or to attentuate the disease. At times when measles is epidemic it is inevitable that the wards of an infectious diseases hospital should become cross-infected, and any remedy for this state of affairs should be extremely valuable. As the epidemic period of measles is rather limited, it was all the more desirable to concentrate on the preventive use of serum, and accordingly no work was done on sero-attenuation of the disease.

For the provision of serum the choice of donors is necessarily limited largely by the age-period of the disease. This was one of the greatest difficulties, and full use had to be made of the few adult patients who were admitted. The donors who kindly provided blood for this work were mainly nurses from other institutions in the city who had the misfortune to contract measles. Two to three hundred cubic centimetres were removed when possible, the time chosen being from the seventh to the tenth day after deferrescence.

The procedure followed in the preparation of the serum was that of Debré and Joannon, the details being as follows:—

1. The blood after removal from the donor was allowed to coagulate at room temperature for 36 to 48 hours. 35 to 40 per cent. of serum was obtained.

2. A Wassermann reaction was performed with each sample of serum.

3. The serum was heated at 56° C. on two successive days.

4. The sterility of each sample of serum was tested by cultural methods.

brought down and the abdomen of the fœtus was now embraced by the ring so tightly that no further progress could be made. Conditions were unchanged for ten minutes, when an inhalation of 6 minims of amyl nitrite was given. For one minute no change could be felt in the consistency of the ring, but at the end of this time traction on the trunk caused easy descent of the fœtus and further examination of the ring was not practicable. Delivery was complete in three minutes. The placenta was retained in the uterus, and as the condition of the patient was poor as a result of antepartum hœmorrhage, the placenta was expressed by Crédé's method, without much difficulty. Hæmorrhage in the third stage was slight. The fœtus was about 1½ months premature, and stillborn. The head was not grossly misshapen. The puerperium was normal.

STEREOSCOPIC RADIOGRAPHY OF THE CORONARY CIRCULATION.

BY JOHN S. CAMPBELL, M.B., B.CH. BELF.,
CLINICAL ASSISTANT TO THE PATHOLOGY DEPARTMENT, ROYAL VICTORIA HOSPITAL, BELFAST; PATHOLOGIST TO THE ULSTER VOLUNTEER FORCE HOSPITALS.

AT a meeting of the Association of Physicians of Great Britain and Ireland held in Belfast in June, 1927, I had the privilege of showing a series of radiograms in stereo of hearts and kidneys injected with an opaque emulsion. In answer to a large number of inquiries, I propose to give a brief account of the technique used and a few observations from a study of the injected hearts.

Technique.

Removal of Heart from the Body.—A portion of the great veins must be removed intact with the heart. This is essential if troublesome leakage from the atrial vessels is to be avoided.

Opaque Medium.—Röntyum, a preparation of barium, was found to give the best results. This substance forms a very fine and stable emulsion. Röntyum, 40 g., is emulsified with distilled water, 75 c.cm.

FIG. 1.

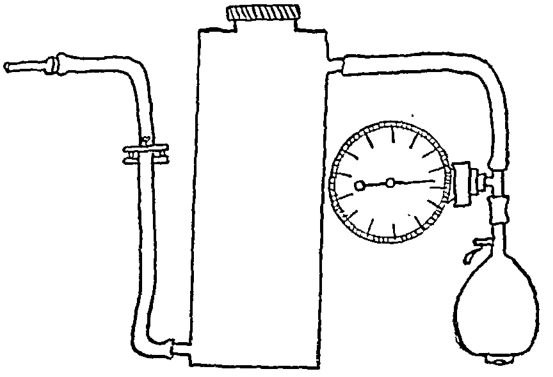

Diagram showing the apparatus.

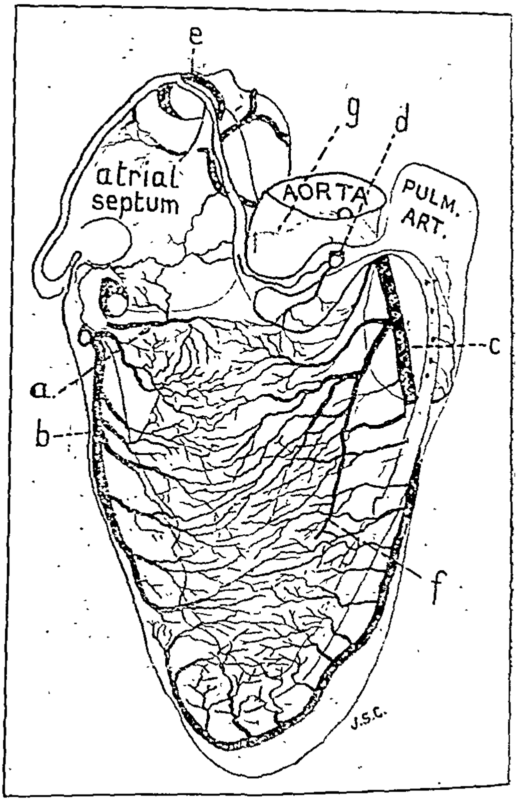
Apparatus.—The diagram (Fig. 1) is self-explanatory. A pressure of 280 mm. of mercury is maintained for three minutes.

Fixation.—After injection of both coronary arteries the chambers of the heart are packed with wool and the organ immersed in 10 per cent. formalin for 24 hours to secure fixation in the best position for stereoscopic examination.

This simple method has been found to give satisfactory pictures when a stereoscopic X ray photograph has been taken of the injected specimen. The skiagrams demonstrate very clearly the finer ramifications of the cardiac vessels, while small variations in their calibre can be readily noted. A fuller interpretation of the skiagrams necessitates detailed knowledge of the minute anatomy of the cardiac circulation, for which I am indebted to the work of Gross.[1] The variations in the distribution of the coronary vessels as noted by him were confirmed, but their occurrence has been greater in my series. The alteration in the relative vascularity of the ventricles which comes with advancing age, and results in a decrease of the blood-supply to the right heart through an increase in the development of anastomotic branches, was also verified. Diminishing vascularity of the heart similar to that found in senility was found to accompany coronary disease.

FIG. 2.



Line drawing from stereophotograph of the cardiac septa (right aspect) showing a septal anastomosis and blood-supply of the A-V neuromuscular tissue. (*a*) Ramus septi fibrosi (*art. to A-V node and bundle*). (*b*) Right coronary, post. descending branch. (*c*) Left coronary, ant. descending branch. (*d*) Origin [illegible] ostii cavæ superioris. (*f*) Artery [illegible] nus limbi dextri). (*g*) Arteria [illegible] a. Kugel[4] describes this branch [illegible] ft coronary in 66 per cent. of his [illegible] er cent. in my series. Origin of [illegible] right coronary, post. circumflex [illegible] cent.); from the left coronary, [illegible] post. circumflex br. 17 per cent. (Gross—8 per cent.).

The Coronary Anastomotic Network.

Removal of portions of the ventricular walls made possible a stereoscopic study of the septal circulation and the supply of the neuromuscular tissue. Fig. 2 illustrates a rich anastomosis in the septum. In this case the ramus septi fibrosi (artery to the auriculo-ventricular node and bundle) is seen to form seven distinct connexions. These are: (*a*) Through its branch to the atrial septum with a posterior atrial vessel, a descending branch of the ramus ostii cavæ superioris, and anterior atrial branches from the right and left coronaries. (*b*) In the interventricular septum with branches from the right and left coronaries, and a branch arising from the right coronary near its origin. Of this last vessel, which occurs in 20 per cent. of my series, I can find no previous mention. Its importance, moreover, merits a fuller description. Leaving the under surface of the right coronary close to its origin, it runs downwards and backwards in the substance of the crista supraventricularis to reach the interventricular septum, where it anastomoses with the septal branches of the anterior descending division of the left coronary (Fig. 3) and, in some instances, with the ramus septi fibrosi. This artery was present in five hearts showing extensive disease of the proximal portion of the anterior descending branch of the left coronary. It may assist in supplying the right limb of the bundle.

Stress is laid on this anastomotic network supplying the neuromuscular tissue because of its importance in the interpretation of clinical findings. Injury to the conducting tissue (heart-block, bundle lesion) is shown on electrocardiographic tracings. Tracings in cases of coronary occlusion show these rarely; in some they are transient.[2] the ordinary blood-supply being apparently able to protect this important tissue. Géraudel[3] reports two cases of Stokes-Adams syndrome in which the ramus septi fibrosi (artery to the node and bundle) was stenosed. My present series includes a case in which partial occlusion of this vessel did not produce a lesion recognisable by the electrocardiograph. This heart showed a well-developed atrial branch of the ramus septi fibrosi communicating with the anastomotic network in the atrial septum.

The attention that is being focused at present on the clinical diagnosis of coronary thrombosis adds interest to some of my cases. I shall pass over them briefly here as a more detailed survey of the series is in course of preparation.

It was observed that an early sign of coronary disease was a narrowing of the lumen of the small twigs of the coronary vessels. This gave these small vessels an appearance of having been nipped just at the point of leaving the parent vessel. Numbers of hearts were found with partial or total occlusion of a coronary artery or its branches. Five of these presented a large area of infarction, others fibrous plaques in the myocardium, while others showed no lesion apparent to the naked eye. These hearts without exception had highly developed compensating anastomotic channels, a beautiful subendocardial network in a case of gross infarction being sufficiently rich to preserve the lining layer of the organ. Two specimens of complete right coronary occlusion are of especial interest. Röntyum injected into these via the patent left coronary artery was found to have filled the occluded right coronary. This occurred through connecting channels chiefly in the interventricular septum.

Clinical and Laboratory Notes.

SERUM PROPHYLAXIS IN MEASLES.

BY D. SAGE SUTHERLAND, M.D. GLASG.,
MEDICAL SUPERINTENDENT, MONSALL HOSPITAL, MANCHESTER; CLINICAL LECTURER IN INFECTIOUS DISEASES, VICTORIA UNIVERSITY OF MANCHESTER;

AND

J. S. ANDERSON, M.D. ABERD.,
SENIOR ASSISTANT MEDICAL OFFICER, MONSALL HOSPITAL, MANCHESTER.

IN recent years attention has been more and more directed to the study of measles, and while an advance has been made in the provision of increased hospital accommodation for the treatment of the disease, the preventive aspect has not received its due recognition. It is 12 years since Nicolle and Conseil, in France, and Park and Zingher, in America, first published the results of their work in this direction, and since then comparatively little additional literature has appeared on the subject. This paper is based on work at Monsall Hospital, Manchester, the opportunity for which was furnished by an epidemic of measles of considerable proportions in that city during the last few months of 1927.

It is well known that the serum of patients convalescent from measles can be used either to prevent or to attentuate the disease. At times when measles is epidemic it is inevitable that the wards of an infectious diseases hospital should become cross-infected, and any remedy for this state of affairs should be extremely valuable. As the epidemic period of measles is rather limited, it was all the more desirable to concentrate on the preventive use of serum, and accordingly no work was done on sero-attenuation of the disease.

For the provision of serum the choice of donors is necessarily limited largely by the age-period of the disease. This was one of the greatest difficulties, and full use had to be made of the few adult patients who were admitted. The donors who kindly provided blood for this work were mainly nurses from other institutions in the city who had the misfortune to contract measles. Two to three hundred cubic centimetres were removed when possible, the time chosen being from the seventh to the tenth day after deferrescence.

The procedure followed in the preparation of the serum was that of Debré and Joannon, the details being as follows:—

1. The blood after removal from the donor was allowed to coagulate at room temperature for 36 to 48 hours. 35 to 40 per cent. of serum was obtained.
2. A Wassermann reaction was performed with each sample of serum.
3. The serum was heated at 56° C. on two successive days.
4. The sterility of each sample of serum was tested by cultural methods.

5. Serum from at least three donors was pooled.
6. The mixed sera were tested by cultural methods.
7. The serum was stored in an ice-chest until required.

The serum was administered subcutaneously and a uniform dose of 10 c.cm. was employed irrespective of age and the length of exposure. No untoward effects were noted, nor were symptoms of serum sickness observed in any case. The details of the experimental work in chronological order are given below.

Experiment 1.—Measles broke out in a scarlet fever ward containing 14 children, six of whom were not recorded to have had measles, and of these, three were adjacent to the infective case, who was, of course, removed to an appropriate ward. The three nearest susceptible children were inoculated on the third day after exposure. Within six weeks the three uninoculated children developed measles along with three other children who were recorded to have had measles previously. The three inoculated children, aged 2, 4, and 4½ years, were under observation in the same ward for 62, 45, and 30 days respectively, and in spite of repeated exposure, failed to develop measles.

Experiment 2.—Three scarlet fever patients occupied a room with accommodation normally for one adult patient. None was stated to have had measles. One child developed the disease and was removed, and the youngest contact, aged 3 years, was inoculated on the third day after exposure and failed to develop measles during 28 days' observation. The remaining patient, aged 5 years, duly developed measles after the normal incubation period.

Experiment 3.—A baby, 2 months of age, was sent to hospital in error in an ambulance along with another infant suffering from measles. Infection was presumed to have taken place, and the baby was nursed in a measles ward, having been given serum on the third day of exposure. No symptoms were noted during observation for a period of 20 days.

Experiment 4.—Following the occurrence of a case of measles in a bed-isolation ward, three children, aged 3, 2, and 4 years, received prophylactic inoculations on the third day after exposure. Six days later another child developed measles, and after a further 11 days the sole remaining susceptible patient developed the disease. The inoculated children were under observation for periods of 51, 32, and 40 days respectively, and showed no symptoms.

Experiment 5.—An infant, 3 months old, in contact with measles at a children's hospital, received serum on the third day after exposure, and was nursed in a measles ward. No symptoms were noted over a period of 47 days.

Experiment 6.—Measles infection appeared in a diphtheria ward, and the only known susceptible children were two brothers, 5½ and 7 years of age. The youngest child only was inoculated on the third day and remained free from symptoms, while the brother developed a typical eruption on the fifteenth day after exposure.

Experiment 7.—Two children unrelated, notified as suffering from laryngeal diphtheria, were nursed in the same steam tent for 24 hours. Unfortunately, one proved to be in the prodromal stage of measles. The other, an infant of 6 months, was thereupon inoculated and failed to contract the disease during a month's observation.

Experiment 8.—A scarlet fever ward became cross-infected with measles. The five known susceptible patients, with ages varying from 2½ to 7 years, received serum on the second day after the occurrence of the case. It was hoped thereby to stamp out the infection. After the usual incubation period, a child stated to have had measles previously, contracted the disease, and, after a similar period, an adult, also stated to have suffered previously from the disease, developed typical symptoms. None of the inoculated children developed the disease.

Experiment 9.—Two days after exposure the only two children who were known to be susceptible in an infected diphtheria ward received prophylactic inoculations. Neither developed measles, and no further cases occurred in the ward.

Conclusions.

1. Measles convalescent serum is a safe and reliable prophylactic remedy, if given in adequate dosage within the first three days of the incubation period.

2. The use of convalescent serum is necessarily limited by the difficulty in obtaining suitable donors.

3. A history of an attack of measles in a child is frequently unreliable. This circumstance limits the absolute control of measles in a children's ward by the use of convalescent serum.

COMBINED VITAL AND NON-VITAL METHOD OF STAINING CORPUSCLES.

BY A. CECIL ALPORT, M.D. EDIN., M.R.C.P. LOND.

(*Medical Clinical Unit, St. Mary's Hospital, Paddington.*)

THE following method of staining blood films is comparatively simple, and with a little experience can be carried out as a routine practice in all cases of anæmia. The original method of staining reticular cells was to take a drop of blood on a cresyl-blue stained slide, cover it with a cover slip and place it in a moist chamber in an incubator for 15 to 20 minutes; then a film was made by moving the cover slip over the slide, and finally it was counterstained with methylene-blue or Leishman's stain. This technique, however, is too complicated for general use. The method described below has the advantage not only of staining the reticular cells with cresyl-blue and the leucocytes with Leishman's stain on the same slide, but the technique is nearly as easy to carry out as staining a film with Leishman's stain only.

The method consists in :—

1. Staining a slide with brilliant cresyl-blue and making a blood film on this stained slide, or staining a drop of blood with cresyl-blue and making a film in the ordinary way.
2. Counterstaining the film with Leishman's stain.

(1) *Technique of Vital Staining.*—There are two ways of staining the reticulocytes: (*a*) Take a clean, grease-free glass slide, pass it through a flame nine or ten times so as to heat it well, and dip it into a glass jar containing a 0·3 per cent. solution of brilliant cresyl-blue in ethyl alcohol; then stand the slide on end for a couple of minutes to allow the stain to dry, and polish it gently on a piece of smooth paper or with a soft handkerchief. It is essential to heat the slide well as this ensures an even spread of the stain, without which the result is not, as a rule, satisfactory. On the cresyl-stained slide take a drop of the patient's blood and make a thin film in the usual way. Wipe off the stain on the reverse side of the slide with a damp cloth. The film can be kept or stained immediately with Leishman's stain.

(*b*) I find that a 0·3 per cent. solution of brilliant cresyl-blue in normal saline, to prevent hæmolysis, with 0·2 per cent. potassium oxalate added to stop clotting, is a quicker and more satisfactory method of staining the reticular cells. Take a large drop of blood on a slide and add to it about the same amount of cresyl-blue from a pipette; mix thoroughly by drawing this solution into the pipette three or four times. Place a drop of the mixture on the end of a clean fat-free slide and, holding another slide at an angle of about 50°, make a film in the usual way. This is necessary in order to obtain a thick enough film, as on account of the dilution of the blood if the upper slide is held too low down the film may be too thin to be satisfactory. The dilution of the blood also allows of an even spread, and the making of a good film becomes a comparatively easy matter.

(2) Cover the film with 12 drops of fresh undiluted Leishman's stain and allow it to stand for two minutes to fix. Add 12 drops of distilled water and stand for 7 to 30 minutes. Wash the film carefully until nearly all the blue colour has disappeared and dry rapidly with blotting-paper. To be successfully stained the film must have a faintly blue tinge in it. Overwashing tends to cause the disappearance of the blue from the granules of the reticulocytes, as brilliant cresyl-blue is very soluble in water; underwashing leaves too much blue in the leucocytes and spoils the effect of the Leishman's stain. The film is permanent and can be put away without necessarily mounting it under a cover-glass.

A film stained with Leishman's stain only, and showing marked polychromasia, will, when stained by the cresyl-blue Leishman method, show with few exceptions reticulocytes in place of the polychromatophilia. This probably indicates that the ordinary polychromasia is merely the ineffective staining of reticulocytes by Leishman's method.

SOUTH DEVON HOSPITAL.—Princess Mary on July 21st laid the foundation-stone of the new wing for extending the South and East Cornwall Hospital, and for providing accommodation for 60 additional patients and about 300 out-patients.

Reviews and Notices of Books.

HOW TO START IN GENERAL PRACTICE.

Being Practical Advice for the Newly Qualified. By ISAAC BRIGGS, M.R.C.S., L.R.C.P. London: John Murray. 1928. Pp. 158. 6s.

So long as a man's outlook in medical practice is not dominated by ideas of profit and loss, he will be all the better for some acquaintance with the principles that underly them. As the author of this excellent book says in the preface, the ethical side of practice is always being impressed upon the intending practitioner, often to the exclusion of business and practical considerations. If a young doctor takes up general practice with a limited capital and no business knowledge of how to use it, he is likely to have experiences that may sour his future outlook, and in any case, is at an unfair disadvantage compared with colleagues who have studied medical practice from a business point of view.

Remembering, then, that ethical considerations come first and will chiefly influence his future happiness, no intending practitioner can be the worse for a knowledge of what Dr. Briggs has to say. The book tells him how to register, which defence societies to join, and what to read, mentioning especially "The Conduct of Medical Practice," published by THE LANCET. He learns how to purchase a practice and is wisely told to guard against the temptation of dispensing with legal aid in doing so. "Amateur law or accountancy are far more expensive hobbies than amateur physic," says Dr. Briggs, and "if a vendor declines an accountant's investigation . . . bid him a courteous adieu." Advice is given as to courses open to those not possessing sufficient purchasing capital, and some useful notes about building societies, architects' fees, and contracts are added. Chapters follow on furnishing of a doctor's house and on renting rooms and garages. Another deals in great detail with methods of book-keeping.

The latter half of the book concerns itself with equipment, instruments, practice bags and, useful to those who intend dispensing, suggestions for stock drugs, lists of prescriptions, and other useful information culled from long experience in general practice.

It has been our melancholy experience to comment on certain American books, in which the authors have called loudly for permission for doctors to enter the field of business competition on equality with all men, to advertise their specialties to all the world, and generally to break through what they consider hampering obligations of old-fashioned and unbusiness-like methods. Dr. Briggs's book is based upon no such false position; nothing in it is in any way incompatible with medical practice as a vocation, and we commend it to those who have a high sense of the dignity of their profession but an unnecessary ignorance of business methods.

PRACTICAL SEROLOGY.

Third edition (1926). By LUIGI VIGANO, Professor in the Royal University of Milan; Assistant Director of the Serotherapeutic Institute at Milan. Translated by E. MARY HEFFER. Edited by C. G. L. WOLF, Addenbrooke's Hospital, Cambridge. W. Heffer and Sons, Ltd. 1928. Pp. 221. 12s. 6d.

THIS little book, which has run through three editions, in Italy covers a field not touched by any book of its size in English. In the course of just over 200 pages a large number of serological methods are described. The accounts are necessarily brief and partly, owing to translation, are not always quite clear. The chapter devoted to the care, nourishment, and breeding habits of laboratory animals contains much useful information. Workers in this country will be disappointed with the chapter on agglutination which gives no reference to G. Dreyer's (or any other) water-bath method for performing the test. The statement that inoculation agglutinins generally disappear from the body three or four months after the inoculation, and the suggestion that primary agglutinins can be easily distinguished from secondary ones by the height of the agglutinin titre will not meet with general agreement. The association of the Weil-Felix reaction with the diagnosis of cerebrospinal meningitis is an error; the test gives no help in this connexion. Four methods of performing the Wassermann reaction are set out; a method for obtaining quantitative results by keeping the amount of antigen and complement constant and using various dilutions of the patient's serum might have been included with advantage. No less than 18 methods are described for the diagnosis of syphilis by means of the flocculation reaction, but there is no guidance offered as to their respective values.

The book gives an interesting insight into the serological methods employed in Italy.

SEX PROBLEMS IN INDIA.

By Prof. N. S. PHADKE, Professor of Mental Philosophy, Rajaram College, Kolhapur. Bombay: D. B. Taraporevala, Sons and Co. 1927. Pp. 348. R.6.

THIS book is an exposition of eugenics in relation to the social conditions and customs of India. It is intended for Indian readers. The author writes with knowledge of his subject, which he is at pains to present, not as a new-fangled Western idea, but as one which, though emanating from the West, is supported in its essential points by numerous texts from Hindu Scripture. Thus Prof. Phadke's clear enunciation of the sociological and moral indications for eugenics in India is heavily supplemented by quotations from Sutras and Shastras, the relevance of which will be better understood by the Hindu than by the European reader. It is interesting to note that, while an advocate of Swaraj, Prof. Phadke holds that the achievement of self-government by Indians will not necessarily result in their immediate and automatic racial improvement. "To hope that a race of fit Indians will automatically arise the moment we are politically free is as ridiculous as to hope that a rich harvest will automatically be yielded when the rains come, even though we may sit with folded hands, taking no trouble of sowing."

Prof. Phadke's book is to be recommended to all Indians interested in the racial future of their country, and especially to the rising generation of Indian medical men.

FILTERABLE VIRUSES.

Edited by THOMAS M. RIVERS. London: Baillière, Tindall and Cox. 1928. Pp. 428. 34s.

THE recognition that many diseases may be due to agents which pass through bacteriological filters and are beyond the limits of ordinary microscopic vision has opened a fascinating field for research, as interesting as it is difficult. There is already a considerable literature on the subject, but it is scattered in various journals, and the treatment of virus diseases in the text-books is brief and uncritical. This volume, therefore, is a timely contribution to pathological literature. Published under the general editorship of Dr. Thomas M. Rivers, it consists of ten chapters, each dealing with a different aspect of the subject, and each written by a worker who is a recognised expert in his particular branch. The first chapter by the editor on some general aspects of filterable viruses is one of the best in the book. It is a sane and balanced presentation of the subject and is enriched by references to 539 articles. Other chapters deal with Filters and Filtration, by Dr. Stuart Mudd; Tissue Cultures in the Study of Viruses, by Dr. A. Carrel; Intracellular Pathology in Virus Diseases, by Dr. Edmund V. Cowdry; Virus Diseases of Man (Poliomyelitis), by Dr. Harold L. Amoss; Virus Diseases of Mammals (Foot and Mouth Disease and Vesicular Stomatitis), by Dr. Peter K. Olitsky; Virus Diseases of Fowls (Contagious Epithelioma), by Dr. Ernest Goodpasture; Virus Diseases of Insects (Sacbrood and Polyhedral Diseases) by Dr. Rudolf W. Glaser; Virus Diseases of Plants, by Dr. Louis D. Kunkel; and Virus Diseases of Bacteria (Bacteriophagy), by Dr. Jacques J.

Bronfenbrenner. Each chapter is accompanied by a bibliography, and there is an adequate index.

It will be noticed that only certain selected examples of virus diseases are discussed, others are mentioned in passing or are omitted altogether. This deliberate selection permits of a more general survey than would have been possible had a greater mass of detail been included in each section. The articles are not all of equal merit or equally judicial, but they are all well informed. Each author has had a free hand and if, therefore, points of disagreement are discovered in different chapters, this is merely an indication of the fluid state of our present knowledge of the subject. The volumes as a whole will be welcomed by all who are interested in virus diseases, and may be recommended as a reliable introduction to this important branch of pathology.

THE LOCOMOTIVE-GOD.

By WILLIAM ELLERY LEONARD. London: Chapman and Hall. 1927. Pp. 434. 18*s*.

Mr. Leonard, a professor in an American University, offers the world this autobiography of an agarophobe. After the onset of the symptom in adult life, he recovered a series of forgotten memories which, he reasonably believes, have a close relation to the phobia. This work of recovery, which occupied seven years, was carried on chiefly by crystal-gazing, and to the obvious objection that the memories were fantasies, he answers by detailed confirmation from outside sources. The "Locomotive-God" was a terrifying visualisation derived from frights in early childhood, and his description of the process of gradual resolution into its elements conforms to what is known of such phenomena and stamps the record as genuine. He wrongly applies the term psycho-analysis to his process of recall, whilst protesting frequently that Freudian elements are absent, but psycho-analysts will perhaps trace the evidence for these elements in such incidents as the compulsion upon his parents to sleep near him with the intervening doors open—a typical infantile situation which may call out for real analysis. The tyranny of the neurosis as it enforced itself upon relatives is adequately described, but unrecognised, by the author; the phobia led to their constant attendance, and in the tangle of cause and effect the regressive infantile need for their presence may well have been a stimulant of the phobia. Indeed, the psychopathologist will find in the story many situations the significance of which is lost to the writer, though this in no way detracts from the instructiveness of this human document. His phobia still persists, and its persistence will be regarded by some as proof that the genesis of the Locomotive-God is not fully revealed. The book has much value; what that value is depends upon the reader. The psychopathologist will doubtless find in it material to confirm his own special theories; the practitioner who tends to despise the neurotic will learn from it the suffering that the latter can undergo; the emotionally well balanced will gain insight into the emotions of the poorly balanced; but the poorly balanced themselves had better avoid it.

JOURNALS.

THE JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXXI., No. 3. July, 1928. Pp. 445–596.—The Fate of Colloidal Iron administered Intravenously, by C. J. Polson (Manchester). A combination of chemical and histological examinations shows that the iron accumulates chiefly in the lungs (where it forms emboli in the vessels) and in the liver and spleen (where it is ingested by endothelial cells).—Virus III., with special reference to the Response of Immunised Rabbits to Reinoculation, by C. H. Andrewes (London). The virus was found by making serial testicular inoculations. Partly immunised (sensitised) animals give a larger local response on reinoculation than either normal or immune animals. The virus survives longer in refractory animals such as the guinea-pig than in actively immunised rabbits.—Normoblast, Reticulocyte, Erythrocyte, by F. C. O. Valentine (London). The reticulum of reticulocytes originally forms the connexion between nucleus and cytoplasm.—The Gram-negative Cocci of the Nasopharynx, by S. P. Wilson (Manchester). Apart from the meningococcus and *M. catarrhalis*, a number of ill-defined forms can be distinguished, the systematic position of which is very dubious.—Cerebral Gliomata, by E. A. Carmichael (London). On the whole, the classification of Bailey and Cushing is substantiated; but it is too complicated and the author prefers a simple division into relatively malignant spongioblastic growths and relatively benign astroblastic tumours.—Continued Fever due to *B. alkalescens*, by J. Smith and A. N. Fraser (Aberdeen). The first recorded infection by this organism: a septicæmia arising after childbirth.—The Temperature of Normal Rabbits, by P. Lazarus-Barlow (London). A valuable series of four-hourly readings on eight rabbits for 23 days. The mean is 102·7° F., with a small but regular diurnal cycle. A deviation of 2°F is significant of something abnormal.—Multiple Zones in the Serum Precipitation Reaction, by N. E. Goldsworthy (Cambridge). Mixtures of horse-serum and the corresponding rabbit antiserum may show several foci of precipitation on either side of the optimal mixture which gives the largest reaction.—The Part Played by Alcohol in the Wassermann Reaction, by C. H. Browning and E. M. Dunlop (Glasgow).—Thrombo-angeitis Obliterans, by R. O. Girdwood (Aberdeen). A man of 29. The fibrosis which mats together arteries, veins, and nerves was a striking feature.—The Gastro-intestinal Flora in Pernicious Anæmia, by L. S. P. Davidson (Edinburgh). There is a great numerical increase in *B. coli*, streptococci, and *B. welchii*, both in the stomach and duodenum and in the fæces. No evidence was obtained that the varieties of these organisms present differed from these found in normal persons.—Tuberculosis in a Dog, due to Infection with a Bovine Virus, by G. S. Wilson and R. Lovell (London). A mesenteric gland in a puppy.—Gummata of the Aorta with Rupture into the Pericardium, by R. J. Wright-Smith (Melbourne).—Gumma of the Heart Wall in an Infant of Six Weeks, by J. W. S. Blacklock and J. A. W. McCluskie (Glasgow).—*Bacillus enteritidis* Infection in Wild Rats, by J. C. Kerrin (Aberdeen). Gaertner's bacillus was found in 11 of 100 wild rats in Aberdeen.—A Simple Apparatus for Filtering Small Amounts of Fluid, by D. L. Johnston (Aberdeen). A piece of Seitz filter is supported half way up a centrifuge tube.—The Cultivation of an Organism from the Spleen in a Case of Banti's Disease, by A. A. F. Peel (Glasgow). A pleomorphic fungus.

The LECTURES ON CANCER given as part of a post-graduate course held locally in the winter of 1926–27 have been published in book form by the Manchester Committee on Cancer. The volume includes also a special report on the results of operation in cases of cancer of the breast, compiled by Dr. John Murray and Dr. Gretta Wardle. The 14 lectures deal with general problems of incidence, causation, and treatment, and include detailed clinical studies of cancer affecting various organs of the body. The 521 investigation on operative results concerned 521 cases of cancer of the breast, of which 375 had been proved histologically to be malignant. They are divided into five classes, according to the stage of the disease at the time of operation. The most interesting records are those of the 183 patients operated on in the period 1910–13. In this group, 40 patients of all classes were alive 10 years after operation, while of the 29 patients placed in class one (early cases) 21 were alive 10 years after operation. It is interesting to r that one or two cases survived 12–15 years a operation and then died of a recurrent cancer. A s proportion of the cases still alive (7 per cent. of total number of living cases) have a recurrence.

This book of 150 pages is apparently issued but the insertion of a preliminary report from Scientific Research Subcommittee reminds reader the financial needs of the fund being raised for ca research in Lancashire, Cheshire, and North Wale

THE LANCET.

LONDON: SATURDAY, JULY 28, 1928.

CANCER: VIRUS OR ENZYME?

NE of the first sessions of the International Cancer ference, which concluded a week ago, was given -as was indeed proper and logical—to a discussion he ætiology of cancer. This discussion disclosed significant fact that wide differences of opinion erning the origin of malignancy still exist among e who have devoted a life-time to the study of the blem. If we revert to-day to this subject it is use two of the papers read by prominent path- ists in this country and the United States of erica appear somehow to have impressed the gination of the daily press, with the result that the lic has again been fed with sensational statements demands to know what it is all about. If we turn he official documents submitted by Prof. A. tch and Dr. J. B. Murphy to the conference— this is the only evidence which we can consider— nd little justification for this outburst in the press. eed, Dr. Murphy's paper is mainly concerned with discussion of a highly technical point—namely, ther the "agent" which produced the filterable ours of the fowl is a "virus" or an "enzyme." do not know what an "enzyme" is, we do not w what a "virus" is; they are little more than tract conceptions made to account for certain logical phenomena. We recognise their presence by results which they produce. The essential problem ented by the filterable tumour of the fowl is not ether the causative "agent" is a virus or an zyme, but its remarkable specificity of action, which ables it to reproduce exactly the same type of mour as that from which the "agent" was obtained. e bulk of Dr. Murphy's paper is concerned with idence which, in his opinion, demonstrates that the usative agent is an enzyme. This evidence consists having prepared from an active filtrate of a fowl umour by repeated precipitation a substance which, if injected, produces again the typical tumour. In the concluding paragraph of his paper Dr. Murphy states :—

> It is hardly conceivable that the active fraction which I have thus succeeded in obtaining, *a substance* purified by repeated precipitations, could carry with it through all these *manipulations* any living organisms or virus. To me the enzyme-like nature of the principle seems to have been conclusively established, but there may be some who would still *maintain* that, in spite of all, the possibility of a virus is not excluded. The final and crucial proof must be the production of the same substance from materials which certainly do not contain a virus. This has been accomplished. By similar technical procedures, I have isolated from such normal tissues as the testicles of normal fowls, not in contact with any tumour-bearing animals, a similar agent with which I have produced the typical tumour, transplantable in over 90 per cent. of fowls.

There Dr. Murphy's paper ends, and the reader is left breathless. It would indeed be a remarkable discovery it it were possible to extract *with a considerable degree of regularity* from the normal testes of normal fowl a chemical substance which, when injected into another normal fowl, would produce *with a considerable degree of regularity* a malignant new growth. It would not in itself solve the problem of malignancy, but would rather present us with a phenomenon of far-reaching significance in its general biological aspects. The perplexing thing is that an observer of Dr. Murphy's acuity of vision does not comment upon this aspect of his work, but is content to use this observation merely as an argument for the enzymic nature of the active tumour-producing principle—a matter of secondary importance. From the reports before us it seems, however, to be Prof. Leitch rather than Dr. Murphy who makes the wider claims for this observation. Prof. Leitch himself has reported that on one occasion he obtained a typical "Rous sarcoma" by the injection into a fowl of a normal fowl pancreas, but that on repetition in numerous experiments he has failed to obtained this result. He has also pointed out very truly that a positive result which can only be obtained once in a large number of negative experiments must necessarily be interpreted quite differently from a positive result which can be obtained with a considerable degree of regularity. A single positive result might conceivably be used as an argument against the virus nature of the agent, although it is perhaps not as conclusive sa Prof. Leitch and Dr. Murphy seem to think; but until we know the percentage of successes which result from the injection of the substance isolated by Dr. Murphy into a number of fowls, and the percentage of successes with which an active preparation can be obtained from the testis of a number of normal fowls, it is impossible to assess the *general* value of his observation. On these points Dr. Murphy is silent, presumably because he has not done a sufficient number of experiments to justify an expression of opinion.

A MEDICO-LEGAL INSTITUTE FOR LONDON.

London has no medico-legal institute, and it must be one of a few of the considerable towns in the world which is in that predicament. The *ninth* series of Methods and Problems of Medical Education, issued lately by the Rockefeller Foundation, gives illustrative descriptions of 24 such institutes, mostly in Europe, with accounts of their methods, together with several essays on germane topics and proposals for progress. They are for the most part substantial departments, generally attached to universities, with large buildings and staffed on much the same scale as a good department of anatomy or physiology. The two British establishments which are described (those at Edinburgh and Glasgow) are arranged on a more modest scale. A study of the whole volume cannot fail to raise the question, Why has London nothing of the kind?

The precise functions which a medico-legal institute discharges vary somewhat from place to place, but their main business is the study of violence, murder, and sudden death, and generally to deal with any pathological matters which arise in connexion with police work. The problems arising out of unexpected death are often very complex, and in some cases—e.g., murder—involve issues which are even more important than accurate death certification. Their study is a specialty, and like other specialties it demands a whole-time devotion if anything beyond a very ordinary standard is to be reached and if any fresh progress is to be made. The nearest doctor and pathologist, though well trained along ordinary lines, may well not be competent to elucidate all the delicate problems which legal medicine presents, and an institute staffed with experienced specialists to provide the necessary special training and knowledge. In London at the present time there is one morbid anatomist who has made himself a medico-legal expert, the bulk of medico-legal post-mortems are made by persons who may not be competent always to meet the difficult points, and there is no place where a man may get the necessary experience. What is needed so badly is a large establishment to which all the coroners' and police work will come—post-mortems, toxicology, sexual offences and the rest—and staffed with men who make it their life's work to study and know and practise the business which they have in hand. Whether it should be a university department attached to one of the larger medical schools, or in the Home Office, or under the chief medical officer of the L.C.C. is not now under discussion. The detection of crime is important enough, and the history of poisoning shows how deterrent has been the fact that the wits of those who find it out have been (as far as we know) generally a little better than the wits of those who do it. There may be a good deal of unsuspected poisoning going on, but as a rule those who meditate its practice seem to be afraid of being found out. An effective institute would promote this wholesome apprehension. But it is equally necessary that the causes of deaths which are unexpected and on the surface inexplicable should be made out as accurately as possible. The man who drops dead in the street is one of the most interesting and instructive objects for the morbid anatomist; he raises a special series of problems which are likely to be solved the sooner if he falls into the hands of those who have made a particular study of him. The frequency with which fibrous hearts are reported as fatty hearts by incompetent examiners illustrates the errors which, almost necessarily, follow the present haphazard arrangements.

Another point of importance has been emphasised by recent changes in coroners' practice. Our knowledge of morbid anatomy rests ultimately on our knowledge of normal anatomy. This we have few chances of studying and our knowledge is correspondingly meagre. Human life in western Europe is now long, and medicine is largely concerned with bodies which have passed their prime and may be degenerated. No one knows the extent of this degeneration, nor what would be found if one dissected carefully the first hundred apparently healthy persons met walking along a London street. Our only chances of getting this essential information are provided by deaths from violence, and it is as necessary that healthy bodies should be examined by the pathologists as that anatomists should have an adequate supply of material. Even with motor-cars and more than 5000 deaths per annum from road accidents, the experience of any one pathologist of violent deaths is very limited, and great advantages would accrue if they could be concentrated into a few specialised hands. Lately, to save expense, coroners have recalled the fact that their business is to find out the cause of death, and have failed to have post-mortem examinations made where that is obvious. In so doing they defeat their object more often than they may think; the real cause of death in a man pulped by a lorry may not be as obvious as it seems, and a surprising number of such fatalities show on dissection some substantial disease which is no doubt an important contributory reason why the accident has happened. But, this consideration apart, it should be frankly recognised that no opportunities of doing post-mortems on normal people should be neglected in the cause of medical science. An institute would do away with the difficulty about fees, and, one way and another, a medico-legal institute for London is a necessity which is long overdue. We are glad to see that the London County Council has promised to look into the matter and we hope its inquiry will be fruitful.

THE MENACE OF THE CLINIC.

THE medico-political issues of to-day give little opportunity for impassioned affirmations and ferocious gestures. The Representative Body of the British Medical Association, which considers these subjects for four whole days every summer, is denied the pleasures of oratory now by the conciliatory efforts of its advisers and now by the complicated nature of their proposals. But there are one or two subjects which still make the blood run faster through medical veins, and the assembly was quickened into liveliness last Saturday by picking up the scent of a possible menace to private practice. At first sight the quarry seemed unworthy of the chase, besides having the best intentions; but the meeting was unimpressed by its innocent and affable appearance, doubtless remembering that similar qualities could be claimed for the first rabbits which entered Australia. The fact that the ladies of Chelsea had politely sought the Association's advice about the best way to administer their clinic for middle-class babies or "paying centre for infant hygiene" in no way softened the hearts of those who, believing that the proper person to advise a middle-class baby about his bath, clothes, diet, and general upbringing was the practitioner who would attend him when he was ill, could not conceive the possibility that that practitioner might welcome in many circumstances a reinforcement in his task. Whilst everyone admitted that for poor people the infant welfare clinic was the best available source of information, it was felt that mothers who were prepared to pay five guineas a year for help with the rearing of their offspring would be much better advised to consult their own doctor—not only from his point of view, but from their own. The spokesman of the Council, Dr. J. W. BONE, said that it was no good trying to stop the setting-up of such clinics, and it would therefore be best to guide them along the best lines. He recommended, therefore, that the Association should define a policy that any further establishment of special paying centres should be for the purpose of education and not for treatment; and that mothers attending them should not do so without the knowledge of the family medical attendant. It may be mentioned that those responsible for the clinic, whose institution started the debate, have laid down exactly this injunction (see p. 210). Mr. BISHOP HARMAN, a member of the Council who supported these proposals, saw no objection to children attending such centres while they were in health. Dr. L. W. BATTEN ridiculed the idea of drawing a distinction between babies well enough to go to the clinic and those ill enough to see their doctor. Where, he asked, does hygiene end and treatment begin? Is regulation of diet a form of treatment, and, if not, how much weight must an infant lose before it is to be classified as sick and denied further advice at its clinic.

The steady constriction of the field of private practice is viewed by all with very natural alarm, and on Monday Dr. E. E. BRIERLEY and Dr. FORBES expressed a general opinion when they urged immediate consideration of the steps to be taken to stop the enclosure of more and more of this field by medical officers of health, by voluntary and rate-supported hospitals, and by clinics. But for the moment we wish chiefly to draw attention to the arguments, set out in the discussion, which bear on the value of clinics to the middle-class public, not forgetting either their menace or their value to busy practitioners. Dr. CHRISTINE MURRELL made a good point when she said that the clinic medical officer has the advantage of having at his hand all the facilities afforded by ancillary organisations, but here she must have been thinking of welfare centres for poor people who need the help of such organisations and not of women whose means allow them to subscribe five guineas a year for advice on the problems of infancy. Dr. E. R. FOTHERGILL insisted that the clinic must be comparatively ignorant of home conditions, but he also was thinking in terms of those whose environment may present the chief elements of risk to health, and not of those whose family circumstances are actually those of the medical officer. The pace of work may, however, prevent the latter from getting the information he ought to have, and, in the words of another speaker, the sight of 20 or 30 similar babies in an afternoon is harrowing to the clinical soul, and advice may tend to become stereotyped unless the adviser is doing a great deal of outside practice as well. The home, said Dr. FOTHERGILL, is where a mother or a child should be treated, and anything that takes her out of the home to consult a strange doctor cannot be in her true interests. But obviously this must depend on the quality of the assistance received from the family adviser, and also on the amount of time that he has at his disposal and on his personal attitude towards pædiatrics. Many practitioners are definitely averse from the task described by Mr. BISHOP HARMAN as sitting down day after day in the home and giving advice about the washing, feeding, clothing, entertainment, and education of infants. Some of them regard pædiatrics as the most important and interesting part of general practice, but others believe that everything of importance about infant feeding can be written on the back of a postcard. While Dr. BATTEN is right in saying that it is a low view of the family doctor to imagine that he only wants to tinker with the baby when he has become sick, the fact remains that those who are keen on the care of infants, and therefore fitted to advise upon them, need not in the long run fear competition. To some the word "clinic" has become a fetish and there is an impression that such places can offer something better than an individual medical man. This is a mistaken view; the fact that the clinic tends to send practice to specialists rather than to the family practitioner is a menace, but one which under the rules of the Chelsea Babies Club is ineffective, the coöperation of the practitioner being required in the future treatment. Dr. BONE said the last word in the matter when he pointed out that the public will certainly be the judges. The resolution reported on p. 195, whilst expressing comprehensible disapproval of paying centres for infant hygiene, will never be effective if the public believes that they fulfil a genuine want.

Mr. TURNER asked the meeting where the establishment of clinics was going to stop. If we had paying clinics for infants why not clinics for adolescents, fathers, mothers, old men, and maidens? He strenuously objected to the private practitioner being made a mere funnel through which patients were poured to some specialist destination; he did not want to be "the whetstone that renders the iron sharp, being itself absolved from the duty of cutting." We agree with him that the family doctor should and must be the principal agent in medical work in this country; but the public has a right to skilled advice and treatment, and it is becoming harder and harder to combine the balanced outlook of the general practitioner with a high grade of knowledge of the more special branches of practice. Dr. H. B. BRACKENBURY was able to tell the meeting on Monday that the General Medical Council is satisfied with the teaching of antenatal examination in our medical schools, but this does not mean that the newly qualified student can offer an opinion as good as that obtainable from an experienced obstetrician—whether at a clinic or elsewhere. Paying clinics will be popular as long as they provide advice that the public feel they have hitherto failed to obtain. But all clinics have inherent disadvantages, and they will cease to be any menace to the family doctor as soon as there are enough practitioners willing and able to undertake the kind of work they do.

Annotations.

"Ne quid nimis."

PAY-BED PATIENTS.

THE Report of the Special Committee, the Pay Beds Committee, of King Edward's Hospital Fund for London, was published last week, its wide reference being "to inquire and report upon the question of hospital accommodation in London for persons prepared to pay more than ordinary voluntary hospital patients." The Special Committee consisted of the following five persons, the late Lord Hambleden, Sir John Rose Bradford, Sir Bernard Mallet, Mr. V. Warren Low, and Prof. Winifred Cullis, but from the unanimous and valuable report, Lord Hambleden's signature is sadly missing.

The Report is largely founded on the replies received to a searching questionaire addressed to those hospitals which provide for pay-bed patients within the area of operations of the King's Fund—namely, that greater London which is included in a circle whose radius is 11 miles from St. Paul's Cathedral. The evidence thus obtained from 80 hospitals, general and special, is summarised in an appendix, from which it may be gathered that the sum of pay-beds in these institutions is 1055, of which rather more than half—namely, 522—are to be found in the special hospitals. The figures will, we think, be a surprise to many who have been unaware how far the pay-bed system had increased of late, but the analysis shows great diversity of practice. There is no uniformity about the fees paid, nor do the charges always cover the same services, nor are the arrangements, speaking generally, comparable; but it is perfectly clear that the demand of the public for these beds under one set of conditions or another is quite unsatisfied, and many witnesses testified to the Committee that a far larger provision of pay-beds is necessary as a valuable adjunct to all forms of practice. A classification of those who would be suitable for admission to pay-beds will be found in the Report, and all must recognise that the time when hospitals were only called upon to provide comparatively simple treatment for the necessitous poor is gone by. The Report says that "with the development of expensive methods of treatment in diagnosis a large number of the middle and professional classes are now unable to pay the full cost of services, some of which are often difficult to obtain outside hospitals." This is a moderate statement of a case which need not be set out at length in these columns, so often have we pointed to the fact that while the rich can buy

and the poor can be supplied with the best medical and (especially) surgical skill in times of emergency, the middle-class group of the community enjoys no such good fortune.

The general message of the Report is that a shortage of pay-beds exists and that it can be best met by a steady extension of existing hospitals or provision of separate hospitals, in both cases a scale of inclusive fees being arranged in proportion to the accommodation required. These recommendations, it will be seen, postulate the expiry of a good deal of time before the present situation can be met, though a mutual insurance scheme is suggested as a ready method of beginning the work. As might be expected from the origin of the special committee, the Report indicates where provision of pay-beds under proper administration can be turned into a source of legitimate revenue for the voluntary hospitals thus strengthening them in their charitable work.

SCIENTIFIC SOCIETIES AND INCOME-TAX.

SCIENTIFIC and professional societies, dependent for their financial existence upon the fluctuating subscriptions of their members or upon past savings, are keenly alive to the liability of their funds to income-tax. Not long ago the funds of the General Medical Council were refused exemption,[1] and now two recent revenue decisions, delivered upon the same lines, have again gone in favour of the Crown. It is high time that the many societies and bodies of this nature took counsel together and made some concerted effort to obtain protection for funds mainly devoted to professional education and scientific research. It is true that these funds are often in part concerned with the organisation of a profession and the qualifications and examination of its would-be members. But it is also true that the country, as a whole, obtains benefit from the creation and maintenance of high professional standards. There is probably no general desire that any funds relating to any form of education should be taxed; there was never a louder call than at this moment for the mobilisation of scientific knowledge in the interests of depressed industries; the yield, moreover, from the income-tax levied on professional and scientific associations must be comparatively trifling.

In order to escape liability for income-tax, a society must be "charitable" within the meaning of the Income-tax Acts and a certain statute of Elizabeth. Legally the advancement of learning is a charitable object, but legally there is no exemption unless the society's funds are devoted not only to charitable objects but to charitable objects only. In respect of the Geologists' Association (one of the two bodies upon whose liability Mr. Justice Rowlatt has lately passed judgment), the Commissioners said that the main function was the combination of members for scientific purposes and mutual improvement and the giving and receiving of instruction among themselves. Naturally these studies, pursued by the members in coöperation, tend to the increase of knowledge and indirectly to the promotion of education generally as well as other objects of public utility. But, while admitting this element of public benefit, the Commissioners nevertheless held that the Association was not a body established for charitable purposes only. They therefore disallowed the claim for exemption, and on appeal Mr. Justice Rowlatt has upheld them. He says they might have decided either way upon the facts, but he declines to say they had no material for deciding in the way they did. He interprets their decision as meaning that the Geologists' Association has for its main object merely instruction inter se: this object has a reaction upon the advancement of learning at large, but this element is not strong enough to take the Association out of the category of a purely private society of private individuals. The other recent case (the appeal of the Midland Counties Institution of Engineers), Mr. Justice Rowlatt thought even clearer. He quoted with approval Lord Watson's phrase in the Civil Engineers' case (decided some years ago), to the effect that exemption depends upon the intrinsic character of the object which a society promotes, and not upon the scope of the benefits which may result from its transactions. When one comes to consider, added Mr. Justice Rowlatt, the inevitable issue whether the purposes of a society are charitable and charitable only, the question which emerges is this: "Is there so much personal benefit to the members, intellectual or professional, as to be incapable of being disregarded?" It may be a substantial object of the society that its funds should benefit the members intellectually or professionally. This use of the funds will have the further object of benefiting the public by calling greater knowledge into existence. But, if the two objects are there, then the funds are not exclusively devoted to the one object. In both these recent cases the Commissioners, whose duty it is to find the facts, have held that both the two objects were present. As the like result may be expected in the case of all similar bodies, and as the refund of income-tax is now being withheld, it is not surprising that the subject is attracting attention in the daily press. Why, it is asked, should exemption from taxation be confined merely to philanthropic bodies? Why should there be no relief for the institutions which represent applied science? These institutions do not devote their funds to the personal enrichment of their members. They contribute to the development of national education, health, and industry. It is probably impossible for them to separate their funds and functions in such a way as to preserve from tax that side of their activities which is exclusively "charitable," while admitting liability in respect of those other activities which are concerned with the non-charitable element of benefit to members. The time has surely arrived for abandoning the dependence of our income-tax law upon the anachronistic definition of charities in the legislation of a queen who reigned happily in an age when income-tax was yet unknown. Parliament should be pressed to frame some fresh and simple provision for the relief of scientific education and research.

VARIATIONS IN THE IODINE AND THYROXIN CONTENT OF THE THYROID GLAND.

IT has been shown by many investigators that the physiological effects produced by desiccated thyroid can be brought about by the injection of pure crystalline thyroxin. The relation of the activity of the thyroid to the iodine compounds which occur in the gland is not, however, yet clear. A study of the effect of the seasonal variations and the influence of geographic distribution on these iodine compounds has recently been undertaken by Prof. E. C. Kendall, of Rochester, Minnesota, who communicated his results at a meeting of the American Association of Physicians held at Washington last May. The importance of considering the iodine compounds other than thyroxin became apparent in the course of the investigation, for the purpose of which 100 lb. of fresh hog thyroid glands have been analysed during the first few days of each month for 20 months. Various samples of thyroid material from different parts of the United States and England have also been analysed. The seasonal variation in the total iodine, already observed by other workers, has been confirmed. In January and February 100 lb. of thyroid may contain 14 g. of iodine; in July and August as much as 40 g. This applies to glands removed from animals in the Middle West. The seasonal variation was not observed in the material obtained from England and Scotland. The amount of thyroxin in these glands has also been determined. The importance of considering those iodine-containing compounds which are not thyroxin is shown by the fact that in the summer, when the iodine is at the highest, the percentage of total iodine in the form of thyroxin is not more than 10 per cent., and in the winter it may drop to less than 5 per cent. Thus from 90 to 95 per cent. of the total iodine in the gland is in some form other than thyroxin. The amount of thyroxin present appears also to be influenced by another factor. Many samples examined of desiccated thyroid had a high content of iodine which was physiologically very active, but from which no thyroxin could be isolated. The physiological activity was not destroyed by boiling with acid, but was destroyed by alkali. This suggested that some difference might be produced in thyroid material by permitting the fresh thyroid glands to stand, and as a result of experiments it was found that some chemical change can occur in thyroxin *not only* when the glands are desiccated, but when they are allowed to stand after being freshly ground. The thyroxin is chemically altered and cannot be isolated, but it is still physiologically active. Further experiments appeared to show that another iodine compound is present in the gland which is destroyed with alkali, is stable at least to some degree to acid, and has the physiological activity of thyroxin. Prof. Kendall suggests that thyroxin may be an intermediate form of the active constituent, and that it must be altered before it can become physiologically active. After the alteration has occurred it manifests the typical physiological activity of desiccated thyroid, but is too unstable to be isolated. This alteration cannot consist merely in a detachment of the thyroxin from the protein, or the thyroxin could be recovered. According to Prof. Kendall, it is likely to be some more deep-seated modification, possibly the attachment of a second hydroxyl group to the thyroxin.

THE RISKS OF SPRAYING PAINT OR LACQUER.

THE whole of the June issue of the *Journal of Industrial Hygiene* is devoted to hazards connected with applying lacquers or paints by spray. This method is rapidly replacing the painting of surfaces by hand on account of the enhanced economy of work and evenness of application. It is associated with risks for the painter arising from the materials used; three substances in particular are concerned—benzene used in lacquers, lead compounds in paints, and silica in vitreous enamels. Two valuable inquiries have been made, one by the Pennsylvania Department of Labour and Industry, and the other by the American National Safety Council. A mass of information so acquired is brought together and here presented in readable form. Benzene vapour in air was determined by passing a sample through nitration acids to form dinitrobenzene; the method is described. Two hundred and ninety-one lacquer sprayers exposed to varying concentrations of benzene vapour were examined, and also 266 sprayers of other materials. First, a stimulation of all blood-making organs, but without increased hæmoglobin, was detected, followed by the usual benzol picture of relative lymphocytosis, but absolute leucopenia, with progressive decrease in red cells. Protection is only to be obtained by limiting the amount of benzol used in lacquers to 0·5 per cent. Lead absorption from sprayed paint was detected among 253 workers. It is recommended that the practice of spraying paints or lacquers containing over 1 per cent. of lead be discontinued, or carried out only when adequate air movement of 150 to 200 ft. per minute past the worker towards an exhaust duct is provided. Indications were obtained of a definite silicosis hazard from spraying vitreous enamels on to metal sheets and castings preparatory to firing; 84 sprayers of such enamels were X rayed, of whom 12 per cent. showed definite silicosis and the other 17 per cent. suspicious indications. The need is stressed for routine medical examination of all workers employed in spray coating with materials containing benzol or lead, or with silica in vitreous enamel coatings.

CEREBRAL GLIOMATA.

IT has been a commonplace of pathological histology for many years that the series of tumours which arise from white fibrous connective tissue reproduce the various stages of development through which fibrocytes pass. At one end of the series is the round-celled sarcoma, in which the infant connective tissue cell persists permanently without undergoing any further differentiation; at the other end the fibroma, composed of the mature form. Two or three years ago Dr. P. Bailey and Prof. Harvey Cushing, of Harvard, pointed out that the group of tumours generally named "glioma" exhibit the same kind of series and between them produce all the embryonic phases through which the developing nervous system passes. They also pointed out that differences in structure were correlated with differences in clinical history; tumours which reproduce the adult or near adult stage differ from those of more embryonic structure in the same way, though not to the same degree, that fibromas differ from sarcomas. Morbid anatomy is generally pretty much the same all the world over, but it is interesting to have these ideas worked out on London tumours. This has been done by Dr. E. A. Carmichael working with 75 specimens accumulated at the National Hospital; his results are published in the current number of the *Journal of Pathology and Bacteriology*, a notice of which appears on p. 172. On the whole he fully confirms the results of Bailey and Cushing. At the same time, he points out that many tmuours are not composed wholly of one type of cell and that it may sometimes be almost impossible to assign a given tumour to any one of their types. It is, of course, equally true that many sarcomas are neither round-celled nor spindle-celled, but a mixture of the two, and to expect tumours of any kind to fall precisely into any series of pigeon-holes is to misconceive their nature and characteristics. The common tumours of the brain represent one stage or another of developing neuroglia, and Dr. Carmichael proposes that for practical purposes they should be divided into two main groups. The *spongioblastic* tumour is made up of a type of cell too embryonic to show any definite neuroglia fibrils; it is often degenerate and causes a reactionary gliosis in the surrounding normal tissue, and hence it is very obvious on naked-eye inspection; it occurs generally in people over 40, has a rapid clinical course, and causes focal signs before general pressure symptoms. The *astroblastic* tumour, on the other hand, is composed of a more adult type of cell with more or less developed fibrils; it is much less vascular, less prone to degeneration, causes no reactionary gliosis, and therefore looks very much like normal white matter and is quite ill-defined macroscopically; clinically, it occurs in rather younger people, has a longer course, usually causes pressure symptoms before focal signs, and is more amenable to surgery and radiation. For the present, at any rate, the refinements of cerebral tumours are for the specialists, but we seem to have here a plain advance in diagnosis and prognosis which should find its place in general medicine.

HOSPITAL COÖPERATION.

WHEN, as appears to be inevitable before long, the boards of guardians are abolished and their functions handed over to the county and town councils, the difficult problem of coöperation between the voluntary and the municipal hospitals, or poor-law infirmaries, will become urgent. Some form of coöperation there must be if waste and overlapping are to be prevented, and it is only reasonable to expect that the representatives of the voluntary institutions should be prepared with proposals likely to appeal to the practical common sense of the country. In Scotland the representatives of the voluntary hospitals have for some time past been in consultation on the subject, and have been asked by the Scottish secretary to form a committee and frame their suggestions. We have received a letter from

and the poor can be supplied with the best medical and (especially) surgical skill in times of emergency, the middle-class group of the community enjoys no such good fortune.

The general message of the Report is that a shortage of pay-beds exists and that it can be best met by a steady extension of existing hospitals or provision of separate hospitals, in both cases a scale of inclusive fees being arranged in proportion to the accommodation required. These recommendations, it will be seen, postulate the expiry of a good deal of time before the present situation can be met, though a mutual insurance scheme is suggested as a ready method of beginning the work. As might be expected from the origin of the special committee, the Report indicates where provision of pay-beds under proper administration can be turned into a source of legitimate revenue for the voluntary hospitals thus strengthening them in their charitable work.

SCIENTIFIC SOCIETIES AND INCOME-TAX.

SCIENTIFIC and professional societies, dependent for their financial existence upon the fluctuating subscriptions of their members or upon past savings, are keenly alive to the liability of their funds to income-tax. Not long ago the funds of the General Medical Council were refused exemption,[1] and now two recent revenue decisions, delivered upon the same lines, have again gone in favour of the Crown. It is high time that the many societies and bodies of this nature took counsel together and made some concerted effort to obtain protection for funds mainly devoted to professional education and scientific research. It is true that these funds are often in part concerned with the organisation of a profession and the qualifications and examination of its would-be members. But it is also true that the country, as a whole, obtains benefit from the creation and maintenance of high professional standards. There is probably no general desire that any funds relating to any form of education should be taxed; there was never a louder call than at this moment for the mobilisation of scientific knowledge in the interests of depressed industries; the yield, moreover, from the income-tax levied on professional and scientific associations must be comparatively trifling.

In order to escape liability for income-tax, a society must be "charitable" within the meaning of the Income-tax Acts and a certain statute of Elizabeth. Legally the advancement of learning is a charitable object, but legally there is no exemption unless the society's funds are devoted not only to charitable objects but to charitable objects only. In respect of the Geologists' Association (one of the two bodies upon whose liability Mr. Justice Rowlatt has lately passed judgment), the Commissioners said that the main function was the combination of members for scientific purposes and mutual improvement and the giving and receiving of instruction among themselves. Naturally these studies, pursued by the members in coöperation, tend to the increase of knowledge and indirectly to the promotion of education generally as well as other objects of public utility. But, while admitting this element of public benefit, the Commissioners nevertheless held that the Association was not a body established for charitable purposes only. They therefore disallowed the claim for exemption, and on appeal Mr. Justice Rowlatt has upheld them. He says they might have decided either way upon the facts, but he declines to say they had no material for deciding in the way they did. He interprets their decision as meaning that the Geologists' Association has for its main object merely instruction inter se: this object has a reaction upon the advancement of learning at large, but this element is not strong enough to take the Association out of the category of a purely private society of private individuals. The other recent case (the appeal of the Midland Counties Institution of Engineers), Mr. Justice Rowlatt thought even clearer. He quoted with approval Lord Watson's phrase in the Civil Engineers' case (decided some years ago), to the effect that exemption depends upon the intrinsic character of the object which a society promotes, and not upon the scope of the benefits which may result from its transactions. When one comes to consider, added Mr. Justice Rowlatt, the inevitable issue whether the purposes of a society are charitable and charitable only, the question which emerges is this: "Is there so much personal benefit to the members, intellectual or professional, as to be incapable of being disregarded?" It may be a substantial object of the society that its funds should benefit the members intellectually or professionally. This use of the funds will have the further object of benefiting the public by calling greater knowledge into existence. But, if the two objects are there, then the funds are not exclusively devoted to the one object. In both these recent cases the Commissioners, whose duty it is to find the facts, have held that both the two objects were present. As the like result may be expected in the case of all similar bodies, and as the refund of income-tax is now being withheld, it is not surprising that the subject is attracting attention in the daily press. Why, it is asked, should exemption from taxation be confined merely to philanthropic bodies? Why should there be no relief for the institutions which represent applied science? These institutions do not devote their funds to the personal enrichment of their members. They contribute to the development of national education, health, and industry. It is probably impossible for them to separate their funds and functions in such a way as to preserve from tax that side of their activities which is exclusively "charitable," while admitting liability in respect of those other activities which are concerned with the non-charitable element of benefit to members. The time has surely arrived for abandoning the dependence of our income-tax law upon the anachronistic definition of charities in the legislation of a queen who reigned happily in an age when income-tax was yet unknown. Parliament should be pressed to frame some fresh and simple provision for the relief of scientific education and research.

VARIATIONS IN THE IODINE AND THYROXIN CONTENT OF THE THYROID GLAND.

IT has been shown by many investigators that the physiological effects produced by desiccated thyroid can be brought about by the injection of pure crystalline thyroxin. The relation of the activity of the thyroid to the iodine compounds which occur in the gland is not, however, yet clear. A study of the effect of the seasonal variations and the influence of geographic distribution on these iodine compounds has recently been undertaken by Prof. E. C. Kendall, of Rochester, Minnesota, who communicated his results at a meeting of the American Association of Physicians held at Washington last May. The importance of considering the iodine compounds other than thyroxin became apparent in the course of the investigation, for the purpose of which 100 lb. of fresh hog thyroid glands have been analysed during the first few days of each month for 20 months. Various samples of thyroid material from different parts of the United States and England have also been analysed. The seasonal variation in the total iodine, already observed by other workers, has been confirmed. In January and February 100 lb. of thyroid may contain 14 g. of iodine; in July and August as much as 40 g. This applies to glands removed from animals in the Middle West. The seasonal variation was not observed in the material obtained from England and Scotland. The amount of thyroxin in these glands has also been determined. The importance of considering those iodine-containing compounds which are not thyroxin is shown by the fact that in the summer, when the iodine is at the highest, the percentage of total iodine in the form of thyroxin is not more than 10 per cent., and in the winter it may drop to less than 5 per cent. Thus from 90 to 95 per cent. of the total iodine in the gland is in some form other than thyroxin. The amount of thyroxin present appears also to be influenced by another factor. Many samples examined of desiccated thyroid had a high content of iodine which was physiologically very active, but from which no thyroxin could be isolated. The physiological activity was not destroyed by boiling with acid, but was destroyed by alkali. This suggested that some difference might be produced in thyroid material by permitting the fresh thyroid glands to stand, and as a result of experiments it was found that some chemical change can occur in thyroxin not only when the glands are desiccated, but when they are allowed to stand after being freshly ground. The thyroxin is chemically altered and cannot be isolated, but it is still physiologically active. Further experiments appeared to show that another iodine compound is present in the gland which is destroyed with alkali, is stable at least to some degree to acid, and has the physiological activity of thyroxin. Prof. Kendall suggests that thyroxin may be an intermediate form of the active constituent, and that it must be altered before it can become physiologically active. After the alteration has occurred it manifests the typical physiological activity of desiccated thyroid, but is too unstable to be isolated. This alteration cannot consist merely in a detachment of the thyroxin from the protein, or the thyroxin could be recovered. According to Prof. Kendall, it is likely to be some more deep-seated modification, possibly the attachment of a second hydroxyl group to the thyroxin.

and the poor can be supplied with the best medical and (especially) surgical skill in times of emergency, the middle-class group of the community enjoys no such good fortune.

The general message of the Report is that a shortage of pay-beds exists and that it can be best met by a steady extension of existing hospitals or provision of separate hospitals, in both cases a scale of inclusive fees being arranged in proportion to the accommodation required. These recommendations, it will be seen, postulate the expiry of a good deal of time before the present situation can be met, though a mutual insurance scheme is suggested as a ready method of beginning the work. As might be expected from the origin of the special committee, the Report indicates where provision of pay-beds under proper administration can be turned into a source of legitimate revenue for the voluntary hospitals thus strengthening them in their charitable work.

SCIENTIFIC SOCIETIES AND INCOME-TAX.

SCIENTIFIC and professional societies, dependent for their financial existence upon the fluctuating subscriptions of their members or upon past savings, are keenly alive to the liability of their funds to income-tax. Not long ago the funds of the General Medical Council were refused exemption,[1] and now two recent revenue decisions, delivered upon the same lines, have again gone in favour of the Crown. It is high time that the many societies and bodies of this nature took counsel together and made some concerted effort to obtain protection for funds mainly devoted to professional education and scientific research. It is true that these funds are often in part concerned with the organisation of a profession and the qualifications and examination of its would-be members. But it is also true that the country, as a whole, obtains benefit from the creation and maintenance of high professional standards. There is probably no general desire that any funds relating to any form of education should be taxed; there was never a louder call than at this moment for the mobilisation of scientific knowledge in the interests of depressed industries; the yield, moreover, from the income-tax levied on professional and scientific associations must be comparatively trifling.

In order to escape liability for income-tax, a society must be "charitable" within the meaning of the Income-tax Acts and a certain statute of Elizabeth. Legally the advancement of learning is a charitable object, but legally there is no exemption unless the society's funds are devoted not only to charitable objects but to charitable objects only. In respect of the Geologists' Association (one of the two bodies upon whose liability Mr. Justice Rowlatt has lately passed judgment), the Commissioners said that the main function was the combination of members for scientific purposes and mutual improvement and the giving and receiving of instruction among themselves. Naturally these studies, pursued by the members in coöperation, tend to the increase of knowledge and indirectly to the promotion of education generally as well as other objects of public utility. But, while admitting this element of public benefit, the Commissioners nevertheless held that the Association was not a body established for charitable purposes only. They therefore disallowed the claim for exemption, and on appeal Mr. Justice Rowlatt has upheld them. He says they might have decided either way upon the facts, but he declines to say they had no material for deciding in the way they did. He interprets their decision as meaning that the Geologists' Association has for its main object merely instruction inter se: this object has a reaction upon the advancement of learning at large, but this element is not strong enough to take the Association out of the category of a purely private society of private individuals. The other recent case (the appeal of the Midland Counties Institution of Engineers), Mr. Justice Rowlatt thought even clearer. He quoted with approval Lord Watson's phrase in the Civil Engineers' case (decided some years ago), to the effect that exemption depends upon the intrinsic character of the object which a society promotes, and not upon the scope of the benefits which may result from its transactions. When one comes to consider, added Mr. Justice Rowlatt, the inevitable issue whether the purposes of a society are charitable and charitable only, the question which emerges is this: "Is there so much personal benefit to the members, intellectual or professional, as to be incapable of being disregarded?" It may be a substantial object of the society that its funds should benefit the members intellectually or professionally. This use of the funds will have the further object of benefiting the public by calling greater knowledge into existence. But, if the two objects are there, then the funds are not exclusively devoted to the one object. In both these recent cases the Commissioners, whose duty it is to find the facts, have held that both the two objects were present. As the like result may be expected in the case of all similar bodies, and as the refund of income-tax is now being withheld, it is not surprising that the subject is attracting attention in the daily press. Why, it is asked, should exemption from taxation be confined merely to philanthropic bodies? Why should there be no relief for the institutions which represent applied science? These institutions do not devote their funds to the personal enrichment of their members. They contribute to the development of national education, health, and industry. It is probably impossible for them to separate their funds and functions in such a way as to preserve from tax that side of their activities which is exclusively "charitable," while admitting liability in respect of those other activities which are concerned with the non-charitable element of benefit to members. The time has surely arrived for abandoning the dependence of our income-tax law upon the anachronistic definition of charities in the legislation of a queen who reigned happily in an age when income-tax was yet unknown. Parliament should be pressed to frame some fresh and simple provision for the relief of scientific education and research.

VARIATIONS IN THE IODINE AND THYROXIN CONTENT OF THE THYROID GLAND.

IT has been shown by many investigators that the physiological effects produced by desiccated thyroid can be brought about by the injection of pure crystalline thyroxin. The relation of the activity of the thyroid to the iodine compounds which occur in the gland is not, however, yet clear. A study of the effect of the seasonal variations and the influence of geographic distribution on these iodine compounds has recently been undertaken by Prof. E. C. Kendall, of Rochester, Minnesota, who communicated his results at a meeting of the American Association of Physicians held at Washington last May. The importance of considering the iodine compounds other than thyroxin became apparent in the course of the investigation, for the purpose of which 100 lb. of fresh hog thyroid glands have been analysed during the first few days of each month for 20 months. Various samples of thyroid material from different parts of the United States and England have also been analysed. The seasonal variation in the total iodine, already observed by other workers, has been confirmed. In January and February 100 lb. of thyroid may contain 14 g. of iodine; in July and August as much as 40 g. This applies to glands removed from animals in the Middle West. The seasonal variation was not observed in the material obtained from England and Scotland. The amount of thyroxin in these glands has also been determined. The importance of considering those iodine-containing compounds which are not thyroxin is shown by the fact that in the summer, when the iodine is at the highest, the percentage of total iodine in the form of

[1] THE LANCET, 1928, i., 715.

The men are not good judges, and well contrived plans for sanitary improvement might often be received with apathy if not obstruction by those from whom their meaning was hidden. Seamen present special difficulties. They are young and strong, but those disabled by bad sanitation drop out of employment and are no more seen, and it is the duty of no one to tell their friends that they were victims of unhygienic conditions which they themselves had never reprobated. So the men do not realise their handicap, yet their death-rate is higher (50 per cent. the Registrar-General has said) in the mercantile marine from disease than that of the ordinary English citizen.

The picture is improving. The men are better off than formerly; food and cooking are better; we learn from Dr. Mussen, for example, that the newer and larger ships at Liverpool are having crew spaces aft, hospital cabins, and washplaces. Yet Dr. Howard-Jones and others of experience tell us that in foreign ships more cubic space is given to the men and more attention is paid to cleanliness *compulsorily*, while similar benefits are only *permissive* in British ships. Some port medical officers find that the prevalence of vermin proves the men careless, but their difficulties are becoming recognised. Their employment is intermittent; not even when employed are they well paid; consequently, they live often in the poorest lodgings of seaport towns, they are still apt to be preyed on by harpies, and all their possessions are in a bag which they carry to their next abode, their ship, which changes perhaps four times in a year. What is there here to raise their standard of comfort or conduct? Fleet Surgeon Home told us recently that the disease-mortality that has decreased most among them in 25 years is that from alcoholism (0·9 to 0·2); does that not argue self-control? They seem to have more deaths from enteric than have other men, and the Registrar-General says their death-rate from violence "is quite beyond the range of land experience." An old Elizabethan song probably expresses the views of all:—

"We care for the merchantmen,
Who do our State maintain."

But do we care enough? If so, why do we leave their health in the charge of the lay Board of Trade? Why have we no one at the Ministry of Health to summarise annually the excellent reports of the medical officers of health of the port sanitary authorities, the only doctors who see the seamen and their conditions, and who can tell us what they really need? We congratulate Fleet-Surgeon Home and Alderman Askew on having sponsored a unanimous resolution at the recent Congress of the Sanitary Institute that this transference of responsibility should occur.

THE ORTHOSTEREOSCOPE.

Of all the uses to which an X ray plant can be put the most indispensable are the diagnosis and treatment of fractures and the location of foreign bodies. It is precisely here, also, that an inefficient plant gives most disappointment, and that the limitations even of a clear and well-defined shadow-picture become obvious. The search for a needle in a heel can still be almost as wearisome as in the days when its very presence was unconfirmed; while, unless views are taken from many angles, which is not always convenient, the evidence that manipulation has restored alignment of bones after fracture may be deceptive. An apparatus that indicates the depth of a foreign body or shows the planes in which the fragments of a broken bone are lying, would meet the one demand which even an elaborate and efficient plant has hitherto been unable to satisfy.

In The Lancet of April 14th, under the title of Stereoscopic Radiography, we noted that an apparatus has been designed to give true stereoscopic projections in the fluorescent screen. We have lately had the opportunity of testing this apparatus and are impressed by the effect obtained. A limb is seen in perfect detail with the position and relation of the component parts in a true perspective. The projections and depressions on the bones are clearly visible; the limb looks as if it were made of more or less transparent material. No effort of eye or imagination is required in order to get the stereoscopic effect, and the image obtained is sharp. The apparatus is extremely compact and is remarkably easy to control. The amount of radiation falling upon the patient is little, if at all, in excess of that necessary in the usual type of apparatus. Protection appears to be satisfactory and the workmanship throughout is good. Without an extensive trial of the apparatus it is impossible to estimate its scope or its limitations. Certainly for fracture work and the location and removal of foreign bodies it will prove invaluable. The diagnosis of the position of a gastric ulcer, or of the site of obstruction in the intestinal canal, might well be rendered easier by a stereoscopic view. As to the radiology of the chest, we understand that several famous continental chest clinics have installed this apparatus. It is used in the upright position, and the screen may be viewed from any convenient distance. Ordinary radiograms can be taken, and a special carrier is available whereby two stereoscopic X ray photographs may be taken within one-tenth of a second of each other.

The Orthostereoscope is installed by Stereoscopic X-Rays, Ltd., of 67a, Baker-street, and will be demonstrated to members of the medical profession by appointment.

THE EFFECT OF EMOTION ON BASAL METABOLISM.

An attempt to study the effects of emotion on basal metabolic rate, pulse-rate and blood pressure is recorded in a concerted study[1] by Dr. H. L. Segal, Dr. H. F. Binswanger, and Dr. S. Strouse of Chicago. The emotional stimulus chosen in all cases was the dread of impending operation and the patients studied were divided into three groups; the first consisted of ordinary operative cases, the second of patients with hyperthyroidism who had received preoperative iodine therapy, and the third of patients with hyperthyroidism who had only received iodine in insignificant amounts or had had none at all. These patients had been in hospital for varying lengths of time and their basal metabolic rates had been determined. A test was done on the morning before the day of operation, and another on the actual day, and observations of the pulse-rate, blood pressure, and emotional state were made at the same time. In the first group no constant relation was found to exist between these factors, and the rise in the metabolism on the morning of operation was negligible. Of the 12 patients in the second group, only five showed outward evidence of emotional disturbance and the increase of basal metabolism on the morning of operation was slight or nonexistent. In the third group, in order to make fair comparison with the other two, the patients were informed on a certain evening that operation would take place on the following morning, but when the morning basal metabolism test had been done operation did not take place. In this group all cases were found to have an increased metabolic rate on the morning of operation, the minimum increase being +12 per cent., and the average increase for the six cases in the group being +41 per cent. The authors consider that this increase is due to an increased production of epinephrin rather to an increased secretion of thyroxin, because the return of metabolism to normal after the fright stimulus had been removed was so rapid. A thyroxin reaction lasts days or even months. The reaction shown would be consistent with increased heat production due to epinephrin, for this is immediate and transient. The authors suggest a practical use for their observations, in that a rise in the basal metabolic rate on the morning of operation might indicate that an insufficient dose of iodine had been given.

[1] Archives of Internal Medicine, June, 1928.

Lord Londonderry, the president; Sir Frederick Eley, the chairman of the Council; and Mr. R. Roy Wilson, M.P., the chairman of the Weekly Board of the Chelsea Hospital for Women, which has been issued to the press, both medical and lay, and in which they place before the London hospitals the importance of taking a similar course, on the ground that it might be of appreciable assistance to the Minister of Health, if these institutions became articulate. The advice is sound, and the sooner it is acted upon the better. It is highly desirable that the voluntary institutions should define their attitude and make their considered proposals without serious delay. The present Minister of Health is so well affected to them, and realises so clearly their value as part of the machinery of the national health, that he would undoubtedly welcome a clear and authoritative statement of what seems to them to be desirable and practicable in the way of utilising those poor-law hospitals which, although they every year become more efficient, are not invariably utilised to their full capacity. Two hospital services side by side are becoming something worse than an anomaly, and every effort ought now to be made to prevent the permanence of such a state of affairs, or the emergence of anything in the nature of a State service to the prejudice of a voluntary one.

The British Hospitals Association has here a great opportunity. It falls naturally to it to tap the opinions of the many distinguished experts who administer the London hospitals and perhaps to follow up that step by initiating a similar inquiry in the provinces. As the greatest hospital centre in Europe, the capital must needs come first, but outside its bounds there are many curative institutions, any one of which is individually almost, if not quite, as important as the biggest of the metropolitan hospitals. Such an inquiry as that suggested will not reveal unanimity, but there is little reason to doubt that it would provide the materials for a workable consensus. Advocates of the nationalisation or municipalisation of the entire hospital service know quite clearly what they want and are determined to press for it, notwithstanding its certain enormous cost and its very problematical advantages. They can best be met by a workmanlike scheme which will bring the rate-supported hospitals into friendly inter-relation with those which depend upon the voluntary support of the public. This should be easy under a scheme which would enable the former to be more completely utilised while stimulating the latter to systematise its finance. For constant and often passionate appeals lend much colour to the impression, so sedulously cultivated in some quarters, that the voluntary system is always standing precariously close to the abyss of bankruptcy. How far that impression is from the truth cannot be too clearly or too widely proclaimed.

HEREDITARY AURICULAR FISTULÆ.

SMALL congenital fistulæ opening on the pinna or in its immediate neighbourhood are not excessively rare, and seldom cause trouble to those whom they affect. They are usually referred either to incomplete fusion between the small tubercles which form the outer ear, not a very satisfactory hypothesis, or to a "branchiogenic" origin of an indefinite sort, an explanation which is definitely unsatisfactory—in fact, wrong. Even if the condition could be shown to be associated with some mal-development in the pharyngeal arches, the arches concerned do not correspond with the branchial arches of gill-bearing vertebrates; these are represented by the third and following arches in the higher embryos, whereas the first or, maybe, the second, are the only arches within whose regions the fistulæ in question can be put. If it is thought absolutely necessary that a piscine nomenclature should be used, the operculum could be dragged in less objectionably, for there is some reason for associating the pinna with the operculum, but none whatever for putting it among the gill-bearing structures. Prof. E. Starkenstein,[1] of Prague, has recently published a short account of specimens of this affection in his own family, of which he has the advantage of possessing records going back to the fourteenth century. The hereditary nature of the condition is clearly brought out in this unusual contribution, and is illustrated by two "trees" extending over three or four generations. Although the families are prolific enough, the numbers given are, of course, too small to permit of any valid conclusions bearing on the laws of heredity; but it can be seen that sex is of no deciding value, that every incidence is immediately preceded by incidence in one or both parents, and that the affection may be one-sided or bilateral. A photograph shows a left ear with a small opening on the front part of the down-turned anterior end of the helix, above the level of the crus helicis. About three-quarters of an inch in front of this and below it is a small swelling, marking thick secretion gathered in the blind end of the track, from which it can be squeezed. The situation described here does not appear to come into line with the normal development of the outer ear, but it is quite easy to imagine a slightly abnormal formation of the second and third auricular tubercles affording a foundation for it, and it would seem that the condition might be put into that very large class of malformations in which the developmental processes must have been on abnormal lines from their inception, and which cannot be harmonised with what occurs in normal formation. However this may be, Prof. Starkenstein offers to students of such matters a class of material which is rarely encountered, and which, in all probability, will well repay close study.

CARE OF THE HEALTH OF MERCHANT SEAMEN.

FOR many years we have been calling the attention of our readers to the health, accommodation, and sanitary conditions of the men of the mercantile marine, and have been able more than once to report the advances that have been made on their behalf; but we feel that improvements are not proceeding rapidly enough and that sanitation is not progressing as fast at sea as on shore. There are two great impulses to improve sanitation, and neither is at its strongest at sea. Insanitary environments are brought to notice by a rise in death-rates or by the absence of fall of death-rates as rapidly in some as in other areas or trades; and as regards housing the death-rates that arrest attention may be, and often are, those of women and children, more susceptible and more continuously exposed to the evil conditions than are their menfolk. Such impetus to improvement does not help seamen, for the Board of Trade no longer publishes death-rates for them, while they live their lives and do their work apart, with no numerous attending crowd of women and children to act, like the white mice in submarines, as sensitive indicators of disaster. Another impulse to improvement is public opinion, and seamen derive little or nothing here. Thus visitors to areas of back-to-back houses are at once shocked, and, loudly contrasting what they see with the amenities of their own districts, awake locally a spirit of reform. But the ships are at sea or in docks, and in these regions, far from ordinary observation, escape public criticism; indeed if this were not so, the accumulation of refuse on board ships in dock, of which port medical officers complain, could not go on being repeated, nor could the old hand-flushed latrines of merchant ships have so long persisted if those accustomed to modern "sanitation" had made frequent visitations. Large passenger ships give their crews small cause for complaint; the trouble is in the tramp and coasting ships with small crews and, let it be admitted, small space. Nor must we forget that all improvements must be at the expense of the owners, and do not as on land bring in increased rent. The owners no doubt vary largely in their sense of responsibility, but medical opinion is dead against the employment, as an argument for nothing being done, that the men have all they require.

---

[1] Med. Klin., May 4th, p. 701.

The men are not good judges, and well contrived plans for sanitary improvement might often be received with apathy if not obstruction by those from whom their meaning was hidden. Seamen present special difficulties. They are young and strong, but those disabled by bad sanitation drop out of employment and are no more seen, and it is the duty of no one to tell their friends that they were victims of unhygienic conditions which they themselves had never reprobated. So the men do not realise their handicap, yet their death-rate is higher (50 per cent. the Registrar-General has said) in the mercantile marine from disease than that of the ordinary English citizen.

The picture is improving. The men are better off than formerly; food and cooking are better; we learn from Dr. Mussen, for example, that the newer and larger ships at Liverpool are having crew spaces aft, hospital cabins, and washplaces. Yet Dr. Howard-Jones and others of experience tell us that in foreign ships more cubic space is given to the men and more attention is paid to cleanliness *compulsorily*, while similar benefits are only *permissive* in British ships. Some port medical officers find that the prevalence of vermin proves the men careless, but their difficulties are becoming recognised. Their employment is intermittent; not even when employed are they well paid; consequently, they live often in the poorest lodgings of seaport towns, they are still apt to be preyed on by harpies, and all their possessions are in a bag which they carry to their next abode, their ship, which changes perhaps four times in a year. What is there here to raise their standard of comfort or conduct? Fleet Surgeon Home told us recently that the disease-mortality that has decreased most among them in 25 years is that from alcoholism (0·9 to 0·2); does that not argue self-control? They seem to have more deaths from enteric than have other men, and the Registrar-General says their death-rate from violence "is quite beyond the range of land experience." An old Elizabethan song probably expresses the views of all:—

> "We care for the merchantmen.
> Who do our State maintain."

But do we care enough? If so, why do we leave their health in the charge of the lay Board of Trade? Why have we no one at the Ministry of Health to summarise annually the excellent reports of the medical officers of health of the port sanitary authorities, the only doctors who see the seamen and their conditions, and who can tell us what they really need? We congratulate Fleet-Surgeon Home and Alderman Askew on having sponsored a unanimous resolution at the recent Congress of the Sanitary Institute that this transference of responsibility should occur.

THE ORTHOSTEREOSCOPE.

OF all the uses to which an X ray plant can be put the most indispensable are the diagnosis and treatment of fractures and the location of foreign bodies. It is precisely here, also, that an inefficient plant gives most disappointment, and that the limitations even of a clear and well-defined shadow-picture become obvious. The search for a needle in a heel can still be almost as wearisome as in the days when its very presence was unconfirmed; while, unless views are taken from many angles, which is not always convenient, the evidence that manipulation has restored alignment of bones after fracture may be deceptive. An apparatus that indicates the depth of a foreign body or shows the planes in which the fragments of a broken bone are lying, would meet the one demand which even an elaborate and efficient plant has hitherto been unable to satisfy.

In THE LANCET of April 14th, under the title of Stereoscopic Radiography, we noted that an apparatus has been designed to give true stereoscopic projections in the fluorescent screen. We have lately had the opportunity of testing this apparatus and are impressed by the effect obtained. A limb is seen in perfect detail with the position and relation of the component parts in a true perspective. The projections and depressions on the bones are clearly visible; the limb looks as if it were made of more or less transparent material. No effort of eye or imagination is required in order to get the stereoscopic effect, and the image obtained is sharp. The apparatus is extremely compact and is remarkably easy to control. The amount of radiation falling upon the patient is little, if at all, in excess of that necessary in the usual type of apparatus. Protection appears to be satisfactory and the workmanship throughout is good. Without an extensive trial of the apparatus it is impossible to estimate its scope or its limitations. Certainly for fracture work and the location and removal of foreign bodies it will prove invaluable. The diagnosis of the position of a gastric ulcer, or of the site of obstruction in the intestinal canal, might well be rendered easier by a stereoscopic view. As to the radiology of the chest, we understand that several famous continental chest clinics have installed this apparatus. It is used in the upright position, and the screen may be viewed from any convenient distance. Ordinary radiograms can be taken, and a special carrier is available whereby two stereoscopic X ray photographs may be taken within one-tenth of a second of each other.

The Orthostereoscope is installed by Stereoscopic X-Rays, Ltd., of 67A, Baker-street, and will be demonstrated to members of the medical profession by appointment.

THE EFFECT OF EMOTION ON BASAL METABOLISM.

AN attempt to study the effects of emotion on basal metabolic rate, pulse-rate and blood pressure is recorded in a concerted study[1] by Dr. H. L. Segal, Dr. H. F. Binswanger, and Dr. S. Strouse of Chicago. The emotional stimulus chosen in all cases was the dread of impending operation and the patients studied were divided into three groups; the first consisted of ordinary operative cases, the second of patients with hyperthyroidism who had received preoperative iodine therapy, and the third of patients with hyperthyroidism who had only received iodine in insignificant amounts or had had none at all. These patients had been in hospital for varying lengths of time and their basal metabolic rates had been determined. A test was done on the morning before the day of operation, and another on the actual day, and observations of the pulse-rate, blood pressure, and emotional state were made at the same time. In the first group no constant relation was found to exist between these factors, and the rise in the metabolism on the morning of operation was negligible. Of the 12 patients in the second group, only five showed outward evidence of emotional disturbance and the increase of basal metabolism on the morning of operation was slight or non-existent. In the third group, in order to make fair comparison with the other two, the patients were informed on a certain evening that operation would take place on the following morning, but when the morning basal metabolism test had been done operation did not take place. In this group all cases were found to have an increased metabolic rate on the morning of operation, the minimum increase being +12 per cent., and the average increase for the six cases in the group being +41 per cent. The authors consider that this increase is due to an increased production of epinephrin rather to an increased secretion of thyroxin, because the return of metabolism to normal after the fright stimulus had been removed was so rapid. A thyroxin reaction lasts days or even months. The reaction shown would be consistent with increased heat production due to epinephrin, for this is immediate and transient. The authors suggest a practical use for their observations, in that a rise in the basal metabolic rate on the morning of operation might indicate that an insufficient dose of iodine had been given.

TRANSMISSION OF FILARIA PERSTANS.

THE tradition that a doctor in the tropics must be observant of the strange phenomena of lesser and unregarded living things which the chances of general practice may bring under his eyes was founded by Patrick Manson. His infectious zeal for inquiry enthused his Chinese hospital dressers, and with their eager help, he made those famous observations on the development of *Filaria bancrofti* in the mosquito which formed the inspiring beginning of the modern science of tropical medicine. The example set by Manson has been followed by disciples of every nation, who though busy, like him, with the press of daily clinical duties, have yet managed to add to our knowledge of parasitology. Dr. Dyce Sharp, in the Cameroon has, almost as if on holiday, carefully observed and engagingly described the domestic affairs of gorilla and family. Moreover, with the simplest of material equipment, he has made valuable additions to knowledge in Manson's own subject of filariasis.[1]

In 1890 Manson found two new filarial embryos in the blood of a negro in the London Hospital who was suffering from sleeping sickness, and named one of these *perstans*. In 1898 the adult *perstans* was found in the mesentery of a Guiana aborigine by Daniels. In 1904 Bastian set out that any metamorphosis which *perstans* might undergo did not require an intermediate host for the purpose. Nevertheless Low, and later Fülleborn, conducted experiments with various mosquitoes, and with flea, lice, and tick, with negative results; except that both noted some development in the mosquito. The systematists were also at work. The proper classification of the worm gave rise to some discussion, and was disposed of only in 1926, when Yorke and Maplestone pointed out that Diesing had differentiated the genus in 1861 under the name *Dipetalonema*. So *Dipetalonema perstans* it must be; but for convenience, however, it is still referred to as *Filaria perstans*. The parasite is found in tropical Africa, and also in British Guiana and in New Guinea. Its principal area coincides with the chief habitat of gorilla and chimpanzee, in both of which apes it has been found. The adult worms are found usually in the root of the mesentery or in the perirenal tissues. The embryos appear in the peripheral blood by day and night, with a tendency to relative day or night periodicity. No more can be said than that in most cases the infestation appears to be harmless.

This was the position when Dr. Sharp began his investigations. In the Mamfe district of the Cameroon the incidence of infection is at least 92 per cent. of the native population. Dr. Sharp found *perstans* to be comparatively rare in the European, who to-day invariably uses a mosquito net at night. He reasoned that the vector of *F. perstans* must have far less opportunity of attacking the European; and since day-biting flies and night-biting mosquitoes attack black and white races impartially when these are unprotected, it was probable that the mosquito net was not the sole barrier against infection, but that the vector must also object to light even at night; for in no other way would the white man be protected while playing cards at midnight—an occasion when mosquitoes may be very active. Dr. Sharp asked his native servant, Kofi, if he knew of a small fly which bit at night only and did not readily pass through a mosquito net, but which must be very common in that region. Kofi quickly produced a very small fly (*Culicoides austeni*), which later proved to be an efficient vector of *F. perstans*. His master discovered in Kofi "a natural fly expert who never forgot or forgave an insect that bit him." He could distinguish by sight various species of culicoides. He knew them well. They fed only at night, and then only in the dark, and their needle-like prick was quite unlike the bite of mosquito or sandfly. Kofi had had to keep fire or lamp alight in his room at night to avoid their bites—then he had made himself a calico tent instead, under which he slept. From this tent, however, Kofi produced next morning 18 of these small flies (*Culicoides austeni*), all full of his blood; the females only are blood-suckers. And so the experiments began. Dr. Sharp declares they were carried out largely by Kofi's enthusiastic and untiring help, his amazing powers of observation, and his first-class vision—a necessity for seeing and catching these minute flies. *Perstans* embryos were found in Kofi's blood, and also in that of the two other houseboys. All these and a fourth, Peter, joined willingly, as helpers and experimental material, in the game of this friendly excursion in natural philosophy conducted in a bungalow in the steamy heat of the Cameroon. Peter was chosen for principal reservoir of *perstans* larvæ, and ready bait and feed for the culicoides vamps. *C. austeni* was discovered to be a determined night-biter—but darkness was essential. A lamp, giving a quarter of a candle power in a 7 ft. long tent was sufficient to discourage her advent. Wind deterred her, rain did not; a full moon gave almost complete protection from her. Captive culicoides were induced to feed in the day time by making the room dark and offering them an arm. Dr. Sharp's white arm was refused, though a black arm was eagerly bitten. A very high degree of humidity was found to be essential to the well-being of the fly and the development of her ova. Dr. Sharp undertook the difficult task of examination and dissection of the culicoides (1·5 to 2 mm. in length) at intervals of time after their infected feeds. He found that in *C. austeni* the *perstans* larva undergoes, in eight days, an ordered development through short thick forms to one thinner form three times its original length. At this stage the larva has reached the fly's proboscis, and escapes thence by stretching and finally bursting the terminal membranous portion of the labrum. Seven per cent. of "wild" culicoides were found to be infected. There is, therefore, strong presumptive evidence that *C. austeni* is an efficient transmitter of *F. perstans* from man to man. Dr. Sharp's observations make it probable that *C. grahami* is also a natural vector of *perstans*. In the Mamfe division of the Cameroon the forest has given way to low orchard scrub or open grass land, and the streams are torrential and tend to dry up after the rains. It is probably the most heavily infected with filaria of any district in the world, though *F. bancrofti* is rare. Dr. Sharp has shown that apart from blood infection, infection of the skin itself with filarial larvæ is very frequent in the natives of all ages and both sexes. It was common to find natives under 16 years of age showing simultaneous infection with leprosy, yaws, *O. volvulus*, and *F. perstans*. The pathogenicity of the latter is not known, but in view of the notably low health condition of the population it is difficult to exclude this high degree of parasitism as an accessory factor of general unfitness.

A PARATYPHOID OUTBREAK.

THE clinical details of the outbreak of paratyphoid fever which occurred in certain districts of Hertfordshire in November, 1927, were recorded in THE LANCET of Feb. 25th last by Dr. Iris Ward, house surgeon at the West Herts General Hospital, to which 43 of the cases were admitted. The prompt steps taken to ascertain and remove the source of infection were successful in limiting the epidemic to 166 cases. In a report[1] to the Minister of Health published to-day Dr. W. Vernon Shaw, one of the medical officers to the Ministry, sets out the details of the story from Nov. 15th, when the Minister received unofficial intimation of the presence of an epidemic of enteric fever in the Hemel Hempstead and Watford districts, until Nov. 24th, by which time 133 patients were safely isolated in hospital, and their homes disinfected and cleaned. On Nov. 16th, the day after his first visit to the district, Dr. Shaw had already elucidated the mystery, and from this date onwards no further spread of infection occurred. The population of the actual area invaded is about 21.000. Bacteriological examination of the water, which is mainly supplied from public sources, yielded satisfactory results. Arrangements for excrement removal, sewage, and refuse disposal are for the most part on modern lines. In the ten years prior to this epidemic there has been little prevalence of enteric fever, either typhoid or paratyphoid, except for an outbreak limited to the inmates and attendants at one of the Metropolitan Asylums Board's Hospitals in Watford Rural District in 1926. During the last week of October, 1927, and the first week of November many cases of illness occurred. These were at first diagnosed as influenza, but on Nov. 11th notifications of enteric fever began to reach the medical officer of health for the districts concerned. In all 129 houses were invaded. In almost every case notified the Widal test gave positive results to paratyphosus B. and the same organism was identified in the urine and fæces of a number of patients. No deaths occurred. Inquiry showed that throughout the infected area the only factor common to the persons affected was milk delivered to them by a retailer whose premises were situated in the borough of Hemel Hempstead. Dr. Shaw visited all the farms on Nov. 15th and could only discover any recent case of illness at W. farm, where one child, K. X., was ill with "broncho-pneumonia." A specimen of blood taken from this child gave a positive Widal to paratyphosus B, and on Dr. Shaw's advice he was removed to hospital with her mother, Mrs. X., on Nov. 16th. The latter within a few days of admission developed a metastatic abscess of the left breast. Her fæces and that of the child were heavily infected with paratyphosus B, and a specimen of her blood reacted with this organism up to a high titre. Mrs. X. admitted having suffered from diarrhœa on or about Oct. 10th, and is regarded as the source of the epidemic. It emerged that from Oct. 23rd onwards she had not only been washing the milk utensils, cooling the milk, and occasionally even milking, but also nursing the sick child, and the potential infection of the milk was doubtless increased by her close contact with the excreta of the child. Pasteurisation of milk at the premises of the retailer was commenced as early as Nov. 12th and was followed by a rapid diminution of the number of fresh cases of paratyphoid fever: but, according to Dr. Shaw, too great reliance was placed on the pasteurisation, which was carried out in a rough-and-ready manner. In the course of the epidemic five roundsmen developed paratyphoid fever, and it is fortunate that none of them appears to have been responsible for personally disseminating infection in the course of delivering milk on his rounds. After the removal to hospital of Mrs. X. and her child on Nov. 16th, further stoppage of the milk from the farm did not appear to be necessary, since other members of the household were examined for infection with negative results: the fact that no further cases occurred justified this policy. Dr. Shaw acknowledges the assistance received from the county medical officers of health, the practitioners of the district, and the officials of the various sanitary authorities concerned.

[1] *Filaria perstans*, its Development in *Culicoides austeni*. Filariasis in the Cameroon, with Special Reference to Skin Infection by Microfilariæ, Trans. Roy. Soc. Trop. Med. and Hyg., vol. xxi., No. 5, February, 1928.

[1] No. 53. 1928. H.M. Stationery Office. Pp. 16. 3d.

The chief lesson to be learnt from the epidemic is the need for immediate laborious investigation in such circumstances of any history of sickness occurring at a dairy farm. Previous to Nov. 16th the child's symptoms had been attributed to the respiratory system and the mother's own mild attack of diarrhœa. which must have been the first manifestation of the infection, was only recalled to memory after the most searching inquiry.

Dr. Ambrose Owen has been awarded the Sir Charles Hastings Prize of the British Medical Association.

Dr. E. K. le Fleming (Wimborne) and Dr. J. W. Bone (Luton) have been selected by the British Medical Association as their candidates for the two vacancies as Direct Representatives of the Medical Profession on the General Medical Council.

INTERNATIONAL CONFERENCE ON CANCER.

JULY 16TH–20TH, 1928.

(Continued from p. 143.)

SURGERY AT THE CONFERENCE.

THE Surgical Section at the conference organised by the British Empire Cancer Campaign had before it two principal subjects for discussion; the first of these was the classification and treatment of bone sarcomata. The forms of sarcoma affecting bone are many and the need for a convenient classification is great. Several of the surgeons from the United States of America described and praised the classification which was devised by Dr. Codman, for the purpose of a Bone Sarcoma Registry; this registry is now under the care of the American College of Surgeons, and to it are sent particulars of cases of bone sarcoma from all parts of the United States. The reports, including the clinical course, the operations, and the microscopical findings, are carefully examined and the cases classified, so that in time there will be collected a large amount of knowledge of a rather rare condition, of which most surgeons see only a few cases. This excellent plan might well be followed in this country, as there is certainly a great need for more knowledge on this subject. At the present time the most diverse views are held as to the nature of some of these tumours; for instance, there was a wide difference of opinion as to the malignancy of the tumour generally known in this country as a myeloma, for more than one American surgeon described it as truly malignant, while several British surgeons declared that, though malignant forms do occur, yet as a rule it is benign, and may be treated successfully in almost all cases by local removal. One speaker objected strongly to the name myeloma, and held that it grew from the endosteum and from osteoblasts, and therefore he suggested that a more suitable name would be osteoblastoma. On this the opener of the discussion stated that he did not believe in the existence of an endosteum; he had never seen it, and the most careful examination had failed to find it. All, however, were agreed that, if an improvement in the results of the treatment of the more severe form of sarcoma of bone can be achieved, it will be only by a recognition of the existence of the disease at a very early stage, and this is only possible if attention be paid to any persistent pain in a bone. If such a pain should fail to respond to simple treatment, it is certain that a radiograph should be taken, and the presence of a bone sarcoma may be revealed. In an early case such as this it may be possible in one way or another to treat effectively the sarcoma, while it is still confined to its site of origin. It may be that experience will show that radiation is the most efficient method of treatment, but it is agreed by all that in the vast majority of cases the early recognition of the disease is essential.

The second subject was the early recognition and treatment of cancer of the stomach. Here also the general cry was: "Let us see these cases early and it will then be possible to find the disease in a condition in which we may be able to remove it completely and so to prevent any recurrence." The same demand for early recognition of malignant disease and thorough treatment has long been made in the case of the breast, and the excellent results obtained with mammary cancer can only be had in cancer of the stomach if the cases are seen early by the surgeon. This can only occur if it is recognised by all that persistent indigestion in a person over 40 years of age should be taken as a sign that something more than mere "indigestion" is present, and that a thorough examination should be made by the use of all the facilities provided by X rays and other diagnostic methods. The skilled interpreter of radiographs will be able to recognise at once, in most cases, whether a simple ulcer or a malignant growth is present. The statistics provided by several speakers showed how delay in the recognition of cancer of the stomach prevented in many cases any chance of the complete removal of the growth and the neighbouring lymphatic glands; in one series of cases, quoted by Prof. Wilkie, there were admitted into the Royal Infirmary of Edinburgh 675 cases of carcinoma during five years, but of these in only 60 cases was a radical operation possible. Early recognition is essential if any real improvement in the results is to be obtained. The later the operation the wider must be the excision and the more severe the operation, with an increase in the shock, and in the likelihood of thoracic and abdominal complications.

There was a little diversity of opinion as to the relation of carcinoma to simple ulcer of the stomach, but most of the speakers agreed that if chronic gastric ulcers were treated by excision, the number of gastric cancers would be reduced.

CANCER AND THE PUBLIC HEALTH.

THE discussions on the public health aspects of cancer on the last day of the Conference revealed a mass of painstaking labour. The achievement, however, was rather that of getting rid of unprofitable theories than in advancing new propositions. An immense amount of useless lumber has been cleared away in preparation for the edifice which will ultimately arise, but it is clear that the foundations of the future edifice are not yet dug.

The first discussion concerned geographical and racial prevalence of cancer. Certain facts were clearly brought out. One of the most important was the difference in mortality from cancer of the breast and uterus among the women of England, Holland, and Italy. For cancer of the breast the death-rate in the Netherlands is a little over one-half that of England and Wales, and in Italy it is about one-half that of the Netherlands. Another point is, that while the death-rate from other forms of cancer is substantially correlated with mortality from non-cancerous diseases, no reliable correlation can be discovered between cancer of the uterus and breast and fatal non-cancerous conditions. Prolonged and exhaustive inquiries from the statistical, clinical, and other aspects have failed to reveal the cause of these discrepancies. They are not due to differences of age or constitution, or to the proportions of married women in the groups. Differences in treatment do not explain them, nor do racial factors, exhaustively studied by many speakers, serve to elucidate the problem. One of the most illuminating papers was that by Dr. Sourasky on the incidence of cancer among Jews. He was able to show that race had nothing to do with it, but he explained the low incidence of cancer of the penis and uterus among Jews by their observance of the Mosaic code. The inference is that a more careful study of environment might bring an answer to some of the problems of geographical prevalence of cancer. The conclusions of most speakers with regard to racial prevalence were tentative owing to insufficient data, but the consensus of opinion was that race could not be invoked in explaining the distribution of cancer mortality.

A discussion on public action in regard to cancer should have as its corollary recommendations on action to be taken. The public naturally want to know what is to be done. What practical answer can the conference give? A perusal of Sir George Buchanan's paper shows that the Ministry of Health is not idle, but he supplies a statement of problems, rather than a categorical answer to questions of practical politics. Indeed, to the question, how cancer can be prevented, the answer can only emerge through continuous intensive study. But, as a result of their studies, members of the conference were able to explode many fallacies such as that diet caused cancer, or that the disease does not occur in native races. With regard to prevention, the only thing which can be done is to attend to general hygiene, remove sources of chronic irritation, and treat conditions which are known to lead to cancer. With regard to therapeutics the outlook is more hopeful. Modern methods of radiation may help to induce patients to seek advice earlier by allowing them to feel that they need not necessarily undergo an operation. Notification of cancer was suggested, but most speakers felt that at the present state of our knowledge it would have no value. A proposal, which although theoretically excellent was thought by many to be unsuitable to English conditions, was the establishment of cancer clinics. There seems to be a prejudice in the minds of the British public against such places. The divergence of views on the subject of propaganda was extremely interesting. Often, of course, the views held were a reflexion of national characteristics. Sir George Buchanan was undisguisedly thankful that propaganda had nothing to do with his department. Prof. Maisin, of Belgium, insisted that the best form of public education was the education of the practitioner. Lectures and popular instructions were only secondary and must be used with prudence. Dr. George A. Soper, of New York, blazed forth propaganda—books, pamphlets, posters in 20 languages, moving pictures and radio, newspapers and "cancer weeks." He reckoned he had reached 41,000,000 people every day for two weeks by one series of newspaper articles. Dr. Reimann, who followed him with cold statistics on the time elapsing between the patient first noticing a pathological condition in the breast and coming for advice, found there was no indication that the educational campaign going on since 1914 had had any effect. The pith of the matter was voiced by the President who warned enthusiasts to beware of fussing over public health. This is a view which appeals to the British public, and whatever sensational methods may succeed elsewhere, propaganda in this country must be adjusted to the prejudices of the people if it is to be effective in influencing their mental outlook.

THE SECTIONAL DISCUSSIONS.

THE main work of the Conference was divided among a number of sectional discussions which took place concurrently in the mornings. Tuesday has already been reported, Wednesday to Friday follow.

WEDNESDAY, JULY 18TH.

CLASSIFICATION AND TREATMENT OF BONE SARCOMA.

Prof. J. EWING (Cornell), opening the discussion, at the Section of Surgery, Sir CHARLES GORDON-WATSON being in the chair, claimed that a classification of the sarcomata of bone had much more than an academic interest. The classification proposed some years ago by Codman, of Boston, who suggested the registry of bone sarcoma, was very convenient, though it was not perfect. This registry had been taken over by the American College of Surgeons. Since sarcomata of bone were rare it was only by an accumulation of the experience of many surgeons that right views could be formed of the true nature of these growths, and the best methods of treatment of the several varieties. The registry had now very full notes of over 900 cases, classified into four classes: osteogenic sarcomata (i.e., sarcomata derived from bone), giant-celled growths, myelomata, and liposarcomata. Prof. Ewing discussed the varieties and explained their relations to one another. As to treatment, Prof. Ewing pointed out that the first and almost invariable symptom of bone sarcoma is persistent unexplained pain in a bone. Such a pain called for a provisional diagnosis of sarcoma, and then a careful radiographic examination would generally detect the presence of the growth, and in this way early treatment was possible. When the signs pointed to a true osteogenic sarcoma of medullary, subperiosteal, sclerosing, or telangietic type the best treatment was probably immediate amputation, immediately preceded, if necessary, by a biopsy. With nearly all other forms of bone sarcoma radiation competed with surgery in treatment. The more malignant the tumour the better was the response to radiation and the worse the outlook from surgery. Bulky tumours and those with much destruction of bone did not give a good result with radiation and amputation should be performed. The more malignant varieties were generally fatal with any method of treatment. If one considered the difficulties of diagnosis, the severity of the standard of treatment, and the high mortality, the conclusion must be drawn that the present-day treatment of bone sarcoma was very unsatisfactory.

Mr. W. SAMPSON HANDLEY (London) said that in the vast majority of periosteal sarcomata of bone amputation was followed by recurrence; he was inclined to think that the use of radium was the best means at our disposal for dealing with them. In one case he employed 500 mg. of radium for 24 hours and the patient was well nine years after. The surgeon must not be afraid of causing necrosis of bone if he wished to be sure of destroying the whole of the growth. Ultimately the necrosed portion of bone would be separated. In children the risk of producing necrosis was small. As to the ultimate result of radium treatment its great value was shown in one case, in which some months after the growth had been destroyed the patient found the limb so useless that he asked to have the limb amputated. This was done and the bone which had been affected with sarcoma was very carefully examined; no trace of malignant disease could be found in it. Out of four cases of osteosarcoma of the ilium three had been cured. The method of treatment was to turn back a skin flap and then a gluteal flap; the projecting mass of the sarcoma was cut off with a chisel, and a ring of radium tubes was inserted in the growth, with some other tubes within the ring.

Dr. WILLIAM B. COLEY (Cornell) maintained that in periosteal sarcoma of bone amputation was practically useless, though it might be employed with the toxin which he had devised. The toxin had a very definite value, though its use required very great care.

Mr. JULIAN TAYLOR (London) said that in order to understand sarcomata of bone it was of the greatest value to make skiagrams of thin sections of the affected bone, and he stated that in all the tumours he had examined the effects to be seen were those of invasion of the various parts of bone by the malignant tumour. That proved that a malignant stimulus had been applied and that the effects upon the various parts of the bone were essentially the same whatever the nature of the malignant growth.

Dr. CHANNING SIMMONS (Boston) praised the American registry of bone sarcoma. He stated that amputation was the best treatment in very early cases. He had found radium very useful, especially where the growth had arisen as the result of trauma.

Prof. FICHERA (Pavia) laid stress on the value of radiograms in the diagnosis.

Dr. FRANKLIN MARTIN (Chicago) explained the arrangements made of the registry of bone sarcoma, and suggested that it might be used not only in Canada and the United States, but also in other countries.

Mr. R. C. ELMSLIE (London) said that primary endosteal sarcoma was the rarest form. The diagnosis of bone sarcoma had to be made partly by the site and partly by the radiogram, but there was only one certain method, and that was by exploration and the microscopic examination of a small portion removed. He considered that in cases of myeloma curetting was a much more valuable method of treatment than many surgeons seemed to think.

Prof. M. J. STEWART (Leeds) expressed the opinion that a giant-celled tumour was a special tumour of bone. He considered it wrong to call it a myeloma, since it arises not from the bone-marrow, but from the fibrous endosteum and osteoblasts. He suggested the name osteoblastoma.

Prof. ARCHIBALD YOUNG (Glasgow) described an interesting case. A young woman had a bone tumour removed from the mandible 12 years ago. Subsequently similar tumours appeared on several bones; eight years ago some of these were removed from the ribs and elsewhere and later still similar tumours affected nearly all the bones. The skull showed Paget's disease. On microscopic examination of the tumours removed both sclerosis and rarefaction were present.

Mr. HANDLEY remarked that Coley's fluid was useful as an adjunct to radiation.

Prof. EWING, in reply, stated that he had been struck by Mr. Handley's method of removing a portion of a bony tumour and embedding radium within it.

SOME PRESENT-DAY MEDICAL ASPECTS OF CANCER.

Sir WILLIAM WILLCOX, who presided at this Section, began by calling on Sir THOMAS HORDER to open a consideration of

Cancer Cachexia.

Although, he said, there were causes enough to explain the condition, these were independent of the presence of malignant cells; the question should therefore not be judged to be solved by assumptions, however probable. He went on to put forward the suggestion that there might be something specific in the cachexia of cancer, study of which might be of service both in diagnosis and pathogenesis. In illustration of this, one had only to assume that the cancer cell might contain an intracellular microorganism which on disintegration of the cell might liberate a toxin of specific qualities; the cachexia produced by benign tumours undergoing necrobiosis would serve as controls. Treatment, he considered, should prolong life without adding to the patient's discomforts and produce the best possible material for surgeons and radiologists to work on.

Dr. WILLIAM HUNTER remarked that the degree of cachexia was nothing now to what it was 30 years ago. He considered all sources of sepsis should be treated besides that due to the cancer itself.

The CHAIRMAN said the subject of cancer cachexia was a very important one and should be approached from the point of view of: (1) cancer toxæmia; and (2) other sources of sepsis. He added that Sir T. Horder had foreshadowed a possible specific treatment.

Sir JAMES DUNDAS-GRANT considered that the general practitioner's point of view—"How can this be cancer if there is no cachexia?"—was a dangerous one.

Alleged Increase of Cancer of the Lung.

Dr. ROBERT HUTCHISON said that the general impression amongst clinicians in recent years was that there was a considerable rise in incidence of primary cancer of the lung. He showed records of autopsies performed at the London Hospital which bore out this statement. As for ætiology he mentioned three theories: 1. The supervention of cancer on the catarrhal changes in the lungs associated with influenza, pointing out, however, that cancer of the lung began often as an acute illness and might simulate influenza. 2. Irritation of the lungs by tar dust from roads. 3. A possible connexion between pulmonary tuberculosis and cancer; this was not substantiated at autopsies.

Dr. L. S. T. BURRELL said that malignant disease of intrathoracic viscera was seen in three main groups: (1) endothelioma of pleura; (2) carcinoma of lung; and (3) sarcoma of mediastinum. He agreed that primary carcinoma of the lung had become more common of late, and said that it often started acutely owing to the growth ulcerating into a bronchus and producing collapse of lung. Diagnosis, he said, had become easier because of: (1) artificial pneumothorax enabling the relation of lung to tumour to be seen; (2) examination by thoracoscope; (3) examination by bronchoscope; (4) X ray examination after injection of lipiodol. In treatment the only possibility of cure lay in lobectomy: X rays and radium temporarily diminished the size of the tumour.

Dr. C. POWELL WHITE (Manchester) read a paper prepared jointly with Prof. SHAW DUNN and showed slides of graphs made from records of autopsies on primary malignant growths of the thorax from Birmingham General and Queen's Hospitals, Edinburgh Royal Infirmary, Glasgow Western Infirmary, Leeds General Infirmary, London, University College Hospital, Manchester Royal Infirmary, all of which with one exception—Leeds—showed an increase in the incidence of intrathoracic neoplasms during the past 25 years.

Prof. T. SHENNAN (Aberdeen) said the occupations of the cases he had examined were varied, therefore of no ætiological value. The predominant growth was a small-celled carcinoma (the oat-seed cell type described by Barnard). In all there were areas impossible to distinguish from short spindle-celled sarcoma. He had himself come to the conclusion that the spindle shape was the result of mechanical influence on the plastic cell substance. As possible predisposing factors he suggested old-standing pulmonary disease and "gassing" during war service. Prof. Shennan then showed slides and microphotographs illustrating his paper.

Dr. W. G. BARNARD (London) showed microphotographs proving that the majority of tumours diagnosed as sarcomata of the mediastinum were in reality medullary carcinomata of lung. He said that histologically parts of a growth might show typical oat-shaped cells, but other parts of the same growth showed transition to carcinomatous tissue—i.e., polygonal cells and tendency to squamous epithelium; oat-shaped cells could also be found in carcinomata.

Dr. LEONARD HILL (London) said he had been feeding mice on different diets and had found the spontaneous cancers of the lung—to which mice were very subject—were uninfluenced by diet.

Prof. DUNCAN GRAHAM (Toronto) endorsed former speakers' experiences in regard to the increased incidence of primary cancer of the lung. He considered the sudden onset of symptoms were due to ulceration of the growth into a bronchus with mechanical obstruction. He did not consider influenza an ætiological factor.

Dr. J. C. TULL (Singapore) and Dr. J. ANDERSON (Hong-Kong) both gave as their experience that primary carcinoma of the lung was rare in their respective districts: they said, however, that primary carcinoma of the liver was commonly associated with biliary cirrhosis, possibly due to the fact that 85 per cent. of patients had had syphilis.

Dr. W. C. MACCARTY (Mayo Clinic) considered the increasing incidence of cancer of the lung as a great problem in the near future.

Dr. A. T. TODD (Bristol) suggested arsenic as an ætiological factor in view of its general use in treatment.

The CHAIRMAN said that it was helpful to get the experience of medical men from all parts of the world, and that it was interesting to know that new growths of the lung were carcinomatous and not sarcomatous in origin.

Dr. HUTCHISON, replying, said that general opinion agreed that there was a definite increase in the incidence of primary cancer of the lung. Little light had been thrown on ætiology; he viewed with diffidence Prof. Shennan's suggestion that preceding lung disease was a factor, since the growth itself set up chronic inflammatory changes. He thought there was no evidence that "gassing" or arsenic favoured malignant growth, and diet was known to have no influence.

BIOLOGICAL EFFECTS OF RADIUM AND X RAYS.

Prof. SIDNEY RUSS took the chair at this discussion, when special reference was made to the factors of wave-length, intensity of radiation, and duration of exposure.

Prof. C. REGAUD (Radium Institute, Paris), who opened, said that experiments on the normal tissues of higher animals showed a varying reaction in different tissues if changes were made in intensity of irradiation and duration of treatment. With regard to human skin, Friedreich and Krönig showed in 1918 that, given the same quantity of radiation, earlier and more marked effects were produced when the dose was given in a shorter time. When a dose was spread over a long time the effect was progressively less. In the latter case, therefore, the total dose should be augmented. But it was a mistake to suppose that the experimental results obtained with human skin could be applied to other tissues. In 1927 Ferroux and Regaud, working with X rays, showed that sterilisation could not be produced in the male rabbit without causing necrosis of the skin. When a massive dose was used, however, it was filtered. On the other hand, sterilisation could be easily and constantly produced without causing any serious and lasting lesion of the integuments if the dose was extended over five days. Behaviour of different tissues varied under different periods of exposure. *The explanation, he thought,* must be sought in the alternation of the radio-sensitivity of the cellular stocks, which were dependent on the renewal processes of the normal and neoplastic tissues.

Prof. H. HOLTHUSEN (Hamburg) said the quality of rays must be chosen according to the depth of the focus to be treated. In the case of superficial diseases soft rays were preferred, while for deep therapy strongly filtered rays of high intensity were preferable. No quantitative rules had been made. One rule which had been impressed upon him was that the skin-tolerance dose should not be exceeded in applying a certain focal dose. It seemed clear that there was no difference between the strength and the biological effect of hard and soft rays within the limits of technically employed rays, including the supra-soft rays. Pathological conditions responded better if the dose of radiation decided upon were spread over a number of days or weeks.

Dr. D. QUICK (New York) read a paper in which his purpose was to correlate some of the experimental findings with clinical observations. In experimental work variations were bound to occur, and no single angle of approach would afford an adequate survey of such a complex subject. There was a wide variety of opinion as to the wave-length which should be employed. In discussing the possible reason of reactions occurring, he said too much was usually based upon physical measurements. Did it follow that the rays which were calculated as being given were all absorbed? He was sure that the proportion of energy absorbed differed with each organ. He did not depreciate the value of biological research, but submitted that there existed an equal need for careful clinical observations, based on trial on the *human* subject.

Dr. G. BUCKY (New York) pointed out the peculiar position occupied by the skin in the matter of response to radiation; it differed from all other organs. He gave results on the skin of the use of 100, 60, and 30 kv.

Dr. R. G. CANTI (London) spoke of the relationship of *radiation effects to the factors* of intensity and time, and said there was a threshold of intensity of radiation below which no biological effect took place. Similarly, there was a threshold of minimum time, which had to be exceeded for results to occur.

Dr. N. S. FINZI (London) confined his attention to the question of the latent period, which he regarded as of probable importance in discovering the mode of action of radiation. The definition of latent period was "the space of time after the *application* of radiations before some of their effects become obvious." The larger the dose the shorter was the latent period. The latent period varied greatly according to the tissue receiving the dose. The salivary glands had a latent period of only a few hours, as shown by the stoppage of salivary secretion. The latent period for dry skin was 17 days—i.e., the time at which erythema began to appear; also, with the same dose, it was the time at which hair *fell* out.

A regrowth of hair took place in three months. Another generalisation he gave was that the longer the wave-length of X rays the shorter was the latent period, and vice versa. But there was a large range of medium wave-length for which the latent period was the same. An important adjuvant was moisture. If the skin was kept moist the latent period was half what it was in the dry state. Heat shortened the latent period, especially moist heat, as also did the presence of metallic salts on the skin.

Dr. L. **Mallet** (Paris) said that gamma rays were specially efficient for epithelioma of the mouth and cancer of tongue, palate, tonsil, and pharynx. In all forms of cervical cancer only X rays gave a good result.

Prof. F. C. **Wood** (Columbia) emphasised the variability in resistance to radiation of all kinds of biological material, and described the method of inquiry being pursued at his centre. Their conclusion was that so long as the rays reached the depth required the actual wave-length was not important.

Other speakers were Dr. S. N. **Waterman** (Amsterdam), Dr. A. **Piney** (London), Prof. W. **Duane** (Harvard), Dr. W. C. **Stevenson** (Dublin), and Colonel S. **Mort** (London).

The **Chairman**, in summing up the discussion, said there was much difference among radiologists as to whether the biological effects of X rays depended on the wave-length. It was a case of attempting to make generalisations when there was no basis for them. The question did not arise in the laboratory, but was primarily due to clinicians. Some workers had gone as far from the clinical as possible, using ova of various organisms and calculating as far as they could the energy absorbed by these ova. Efforts were now being made to settle the question without biasing the mind by the use of ova.

OCCUPATIONAL CANCER.

The Section of Pathology, Statistics, and Public Health met under the Presidency of Prof. W. S. **Lazarus-Barlow**.

Drs. J. C. **Bridge** and S. A. **Henry**, of the Home Office, presented a statistical review of industrial cancer in this country. They recommended, as the only effective prophylactic measure, the substitution of innocuous bodies for those with known carcinogenic properties. If this were impossible, early detection and treatment were the only measures. Inquiries had not elicited a single case of cancer in the X ray industry. They suggested that research into occupational cancer of the skin, especially among women, would yield valuable results.

Dr. T. H. C. **Stevenson** (London) spoke of the importance of social distribution; nonconformist and Anglican clergymen occupied the first and second places in a list of 178 occupational groups arranged in reverse order of cancer mortality, while Roman Catholic priests came sixteenth. The certified mortality of the clergy from syphilis was also remarkably low. Comparison between cancer and alcoholism as measured by cirrhosis of the liver, showed similar but less striking results, and Dr. Stevenson concluded that both syphilis and alcohol had a carcinogenic influence.

Prof. G. **Schmorl** and Dr. O. **Rostoski** (Dresden) described the endemic lung cancer of the miners of Schneeberg; they regarded the anthra-cochalicosis scars from which the men suffer as pre-cancerous and left undetermined the primary causal factor. The radio-active dust in the Schneeberg rock might play a part. In six cases multiple primary tumours had been found, and in four there was a latent period, after ceasing work, of 10–18 years.

Dr. **Alexander Scott** (Broxburn) described the more prevalent lesions caused by semi-refined and crude mineral oils and paraffin—viz., papular dermatitis, erythrodermia, and epithelioma. The cancer incidence in the works of Scottish Oils, Ltd., among 5000 men, was less than 0·1 per cent. per annum. The chief predisposing factors were age, length of service, and idiosyncrasy. Early detection, by periodic examinations, was the most valuable prophylactic measure. Multiple primary growths were common.

Mr. A. H. **Southam** (Manchester) gave an account of mule-spinners' cancer, in the ætiology of which idiosyncrasy and dry skin played an important part. The condition could easily be detected at an early stage and excision was satisfactory except in the case of the scrotum, where glandular involvement was more frequent. Multiple primary growths were occasionally encountered.

Dr. L. **Carozzi** (Geneva) discussed occupational cancer, pointing out the inadequacy of present methods of detection. He pleaded for an international medical inquiry on uniform lines, and for a set of guiding principles for revelation and detection of the injurious element in each "carcinogenic" industry.

Dr. A. F. **Sladden** (Swansea) described the epithelioma of South Wales patent-fuel workers, ascribed to gas-works pitch. Usually the growths were superficial and of low malignancy. Systematic medical inspection and prompt removal of warts were important prophylactic measures. The scrotum was the most dangerous area.

Prof. W. J. **O'Donovan** (London) presented a clinical review of occupational skin cancer due to tar, arsenic, oil, and X rays. He pointed out the frequency of a latent period and of multiple primary growths. The prognosis for early cases of tar cancer was very good, and treatment by flat plates of radium was satisfactory. The possibility of actinogenic carcinoma required investigation. He pleaded for a centralised record of amputated carcinomatous hands.

Dr. W. M. **DeVries** (Amsterdam) said that occupational cancer was rare in the Netherlands; cases had occurred in briquette factories, where pitch-dust was in the air.

Dr. F. L. **Hoffman** (U.S.A.) discussed the statistics of cancer incidence and mortality among industrial workers. Estimation was difficult in America because the men very frequently changed from one establishment or from one occupation to another. Dr. Hoffman had been unable to find any record of a case of cancer among lead workers.

Dr. E. L. **Kennaway** (London) discussed statistical data of 921 fatal cases of cancer of the penis and scrotum; the ratio of scrotal cancers to cancers of the penis was lowest among agricultural workers, lower in clerical than in manual workers, and lower in those doing light than heavy work. He suggested that cancer of the scrotum affected especially those who washed least and were exposed to the dust of towns.

THURSDAY, JULY 19TH.

RELATIVE VALUES OF SURGERY AND RADIATION.

Mr. J. P. **Lockhart-Mummery** took the chair at the resumption of the discussion, commenced on Tuesday morning, on the relative values of surgery and radiation in the treatment of cancer of the cervix uteri, rectum, breast, and buccal cavity. Prof. **Burton Lee** (New York), opening, spoke on conservatism in the treatment of

Primary Operable Cancer of the Breast.

He held that conservative surgery deserved as much credit in his results as radiation therapy, and preferred the combined use of the two methods to radical surgery with radiation. Radium was more effective in mammary cancer than X rays; it was especially suitable for patients who also had an intercurrent chronic disease and for those who rejected radical surgery.

Mr. W. **Sampson Handley** asked: 'Can either radiation or operation alone cure breast cancer?" He showed slides proving that surface radiation could destroy or arrest the growing edge of a group of permeated lymphatics, but concluded that, owing to the great extent and depth of the surface to be treated, it was unsafe to trust to radiation alone. Although the primary growth and the enlargement of the glands might disappear dissemination continued. Operation alone might at first sight appear to be sufficient, but an analysis of his recurrences showed that breast cancer, when it came to operation, was usually already a thoracic disease, and therefore that no operation was complete unless a systematic attempt were made to deal with the intrathoracic extension of the disease by buried radium. For the present surgery and radiology must be colleagues, not competitors. Buried tubes generally relieved, and might cure, recurrent breast cancer when the surgeon was helpless. For supraclavicular recurrence a combination of excision with buried tubes gave the best results, but it was useless to try to excise fixed supraclavicular glands.

Dr. **ROBERT KNOX** (London) compared Dr. Janet Lane-Claypon's figures of the results of surgery in 2000 cases with those of a small series of patients treated with X rays. Surgery gave appreciably better results in early cases, but in second-class cases the rays seemed to hold the advantage with 53·6 per cent. of cures against 42·1 per cent., and in the worst cases there was no comparison. Buried radium had not yet proved its value.

Mr. **GEOFFREY KEYNES** and Dr. **J. H. D. WEBSTER** (London) summarised papers which appeared in THE LANCET of July 21st and 14th respectively.

Cancer of the Mouth.

Dr. **DOUGLAS QUICK** (New York), in his opening paper, said in no other group of cases was radiosensitivity so important as in this; the more adult the type of a growth the more resistant it was. Treatment by external radiation would produce complete regression in the more embryonal types of growth, but for squamous-celled carcinoma the application of radon in gold capillary seeds was also necessary. This method, in his clinic, was applied, in the maximum intensity consistent with tissue tolerance, to the local lesion and to both sides of the neck. Mouth hygiene was important, but bad teeth should not be extracted until after irradiation had produced its maximum effect. Prolonged moderate doses were preferable to short intense ones. Surface applicators within the mouth were not recommended. Surgery was not used in direct treatment, but was often a necessary auxiliary to give access to the tumour, to remove bone in cases of secondary invasion, and to remove bulky masses after irradiation.

The treatment of metastases of the neck glands was more important than that of the primary growth. External radiation was sometimes assisted by buried seeds; the 4-g. radium pack was better than X rays, but good X rays were better than inadequate radium. Once the disease involved both sides of the neck it was regarded as incurable.

Mr. **STANFORD CADE** (London) concluded, from a study of 50 cases, that the treatment of election in mouth cancer consisted of three stages: radium therapy of the primary growth, surgical removal of the cervical glands, and post-operative distance-irradiation of the cervical area. Radium gave the only hope in metastatic involvement of the neck.

Prof. **G. E. PFAHLER** (Philadelphia) described the use of pure γ radiation, which was painless on application, produced no mutilation or constitutional symptoms, preserved the function of the tongue, and usually caused the disappearance of metastatic lymph nodes.

Dr. **B. E. ROSE** preferred the diathermy knife for inoperable growths, with irradiation after about a month. Inoperable growths should be treated by radium unless the alveolus were extensively involved, when they should be left alone. The gland fields should be excised if possible and the wound irradiated, but the results of irradiation on inoperable glands were bad.

Evaluation of Statistics.

Dr. **JANET E. LANE-CLAYPON** (London) laid down in her opening paper the fundamental necessities of any statistical inquiry. Only by rigorous statistical methods, she held, was it possible to estimate the advisability of modifications in practice or the value of other agencies.

Prof. **F. C. WOOD** (Columbia) and Prof. **JÜNGLING** (Stuttgart) pointed out the urgent necessity of minute histological subdivision of the various classes of patients in assessing the value of various therapeutic methods. The former postulated that deaths of untreated or rejected patients should be taken into account, and the latter pleaded for an international standard, without which it was impossible accurately to correlate one set of figures with another.

CHEMOTHERAPY, WITH SPECIAL REFERENCE TO LEAD.

Sir **THOMAS HORDER**, who presided at a discussion on the lead treatment of cancer and other methods of chemotherapy, appealed to the speakers to deal with the issue on a clean slate, dismissing from their minds any attempt at prejudgment on ill-digested material.

Prof. **BLAIR BELL** (Liverpool) read the paper which appears on p. 164 of our present issue.

Prof. **F. C. WOOD** (Columbia) thought no one would deny that lead would have an effect on malignant disease in the human subject, but he considered that a greater effect followed X rays. There were cases that yielded entirely to lead. Both lead and gold colloid had been used by him in experiments on rats. His conclusion was that the optimum period for those metals was after the first dose of X rays. The fact that tumours did not alter in size did not mean that they had not been seriously damaged by the treatment and their growth checked.

Dr. **BURTON SIMPSON** (Buffalo) spoke of 19 cases of malignant disease which had been treated with colloidal lead, prepared according to the Blair Bell method, all in an advanced stage of the disease, and had already had surgery or radiation or both. Careful urine and blood analyses were made each day. No clinical improvement was observed in any of the cases, but very soon after the administration there was a severe toxic action on the blood, with secondary anæmia. Nausea and vomiting were frequent, and some of the patients had pronounced jaundice. Only one of the 19 cases was now alive. The treatment had now, owing to the suffering of patients, been abandoned at the institute. Dr. Simpson said this unfavourable impression was supported by all whom he had heard from on the subject.

Prof. **WALTER DILLING** (Liverpool) thought that no final estimate of the therapeutic value of lead was likely to be reached for a considerable time. Lead seemed to exert a special action on growing tissues of embryonal type and sublethal concentrations of lead ion retarded growth, particularly in young animals. His experience was that while lead therapy produced marked benefit in some cases of malignant disease, it left others quite uninfluenced for good. It could not be regarded as parallel to the effect of arsenic in syphilis. Even slight modifications in the routine of preparation rendered the colloid less safe. He showed the results obtained by Prof. Heilbron, of Liverpool, in testing the toxicities of various organic lead complexes. Safe injections were colloidal lead phosphate, with three equivalents of sodium acetate and colloidal lead selenide. He related the results of searches for lead in normal tissues and found that spleen, liver, lung, and kidney contained the greatest proportion.

Mr. **BASIL HUME** reported the results of an investigation by a committee of St. Bartholomew's Medical College, every care having been taken to follow closely the Liverpool method, Prof. Bell having expressed his full approval of the method after a visit. He gave the details on which the following conclusion was based. In 13 cases treated by lead alone 11 died, after an average life from commencing the treatment of 13 weeks. The two survivors (carcinoma of breast) had not improved. Seven patients had deep X ray therapy after preliminary injections of lead colloid. In one case the lead was injected into and around the growth, as the patient was not suitable for the usual method. Of the other six, one received a full first and second course, two a first and a partial second course, and in the other three the whole or part of the first course only. In none of them was improvement demonstrable while under lead treatment. In a majority of the cases the growths increased very rapidly under the treatment, but none of the patients seemed to have died as the result of acute or chronic lead poisoning.

Dr. Stanley Wyard (Cancer Hospital, London) referred to his work on eosin and selenium, and said that success in treating cancer in animals by these had been claimed. No metal had been found by Caspari to be more potent than others. Prof. Bell had claimed better results from lead treatment than had any other worker. At the Cancer Hospital 56 cases had been treated with lead colloid, and the average duration of life after treatment was commenced was five months, but after receiving 0·3 g. of lead the average life was 7 months 3 weeks. Of 40 patients who received sufficient lead 23 died, 10 were worse, 6 showed no change, 1 was somewhat improved.

Dr. G. Loewy (Paris) referred to the finding of Waterman that lead had a curative action on transplanted rat cancer. In every human case, however, lead caused grave intoxication. He had been using colloidal oxide of lead in glycogen in an isotonic solution of 5 per cent. on dogs, which showed very fair toleration to it in a dose of 4 mg. per kilo of body-weight. The toxic dose was 5 mg. Clinical tests showed a remarkable human tolerance to the colloidal lead with glycogen, and the best dose was probably 50 mg. Women were more susceptible to it than men; it was stable and could be preserved for several months. No cure had, however, been obtained with it, but its innocuousness led him to resolve to continue its use.

Dr. A. P. Thomson (Birmingham) said that in 55 cases treated by lead the treatment seemed to influence the progress of the disease favourably in 15, though in most only temporarily. By the system of trial and error he thought it was possible to know within a short time of commencing the treatment whether it was likely to be successful. In the cases which improved the hæmoglobin had never fallen very low. Patients were not now given as large a dose as Blair Bell originally suggested.

Dr. H. F. B. Fry (London) spoke of the pathological changes seen by him in the fatal cases treated with lead by Dr. Wyard, especially in the kidneys and liver, which were most probably due to the lead.

Prof. Bell, in reply, remarked that little had been said on chemotherapeutical principles; the discussion had turned largely on clinical details. In Liverpool scientific curiosity was not allowed to outrun humanity, and for that reason attention had not been confined to lead alone; a goodly proportion of the 1000 cancer cases treated there had had deep X ray therapy in addition to lead. Every patient must be individually treated or satisfactory results could not be expected. Why was it that patients coming to him from London had been imbued with a fear of terrible reactions occurring? These allegations had been made in *Nature*, and that journal had refused to insert his rejoinder. He had brought the treatment to the state that made reactions practically negligible. The size of the growth after treatment was no criterion of its malignancy, for it might be cystic or necrotic. Nature did not proceed by leaps; one must not look for the miraculous. In answer to Mr. Hume, it was true he did what he could to help the work at St. Bartholomew's; his complaint there was that in 15 cases only half the treatment had been given, and conclusions based on these were not fair.

Dr. T. Lumsden (Lister Institute) gave an exposition on tumour immunity and the position of the attempts to kill cancer cells without damaging normal tissue. He suggested that those who treated tumours with radium should not try to get rid of the local growth too hurriedly, so as to cause sloughing, otherwise immunity was hindered.

Prof. F. Bang (Copenhagen) read a paper setting out the results of minimal optimal doses of metallic salts in increasing the defensive mechanism of the body.

Dr. M. Copeman (London) pointed out the good effect of surface applications of fluoresceïn prior to a mild dose of X rays in carcinomata. He showed a number of slides setting out the favourable results, and advocated an extensive trial of the method.

The Chairman, in summing up, dealt with three questions which had been raised in the discussion: (1) Have any patients got well after treatment by lead and (not to quibble) as a result of it? The answer, he thought, was in the affirmative. (2) Can we undertake the responsibility of advising patients to undergo lead treatment? I feel, he said, we have not yet arrived at the point of safety which will enable us to do this. (3) What are the next steps to take? Further search should be undertaken for lead preparations less toxic than those now in use, with the hope of widening the margin of safety, at present dangerously small.

Friday, July 20th.

Early Recognition and Treatment of Cancer of the Stomach

Sir Berkeley Moynihan opened by remarking that the symptoms described in the text-books were those of well-established disease, with organic changes so firmly rooted that there was little chance of complete removal of the growth. The early symptoms varied enormously in different cases. In some the onset of the disease was rapid and even in a very few weeks the tumour was found to be beyond the reach of the surgeon. In some cases the symptoms closely resembled those of duodenal ulcer, while in others they were simply those of dyspepsia, and might be temporarily improved by medicinal treatment. In other cases, again, the symptoms were those of obstruction, at either end or in the body of the stomach. Hæmorrhage might be an early and severe symptom, and sometimes a diagnosis of pernicious anæmia was made, while cases had been diagnosed as suffering from malignant disease of the stomach when the disease had really been pernicious anæmia. Thus it could be seen that the clinical picture was so various and so multiform that by observation of symptoms alone a correct diagnosis might not be possible. Different opinions were held as to the relation of cancer of the stomach to simple ulcer; but there could be no doubt that cancer might develop on a gastric ulcer, for when operating for gastric ulcer the surgeon might find that at one part of the simple ulcer there was a carcinoma; if the case had been seen later the malignant growth would have spread throughout the whole of the simple ulcer. It was important to recognise that cancer of the stomach, like cancer elsewhere, was certainly a local disease, and while it was small it was curable by operation. If the disease was allowed to reach a stage of extensive development the chance of complete removal was greatly diminished. In any cases occurring in a patient over 35 an early radiological examination was imperative, for in this way only was early diagnosis possible. The early infiltration of the muscle caused a loss of movement at the affected part. In any case of doubt an exploration of the stomach was essential.

Dr. A. F. Hurst (London) said that there could be no doubt that a chronic ulcer of the stomach could become malignant. He laid stress on the importance of looking for occult blood in the stools, and he agreed that X rays generally gave such a clear picture that the diagnosis was certain. The achlorhydria of cancer of the stomach was probably due to a chronic gastritis which preceded the appearance of the malignant growth. Hitherto the early diagnosis and treatment of chronic gastric ulcer had alone been considered in discussing the prophylaxis of cancer of the stomach, but it now appeared probable that chronic gastritis was a much more common precursor. It could be prevented by dental hygiene, the treatment of oral and nasopharyngeal sepsis and common sense dietetic rules. When present it could be cured by removal of the cause, together with lavage every morning with dilute hydrogen peroxide until no more mucus is removed.

Dr. EDMUND SPRIGGS (Ruthin Castle) pointed out that, though the newest methods, such as X rays and chemical tests, enabled us to recognise the presence and nature of the lesion at an early stage, the first suspicion must arise from the study of the earliest symptoms. It was not sufficient to say that a patient had indigestion and to treat this merely by medicine or diet; indigestion was not a diagnosis; it may be due to any one of many causes, but it must be remembered that the earliest manifestations of cancer of the stomach in no way differed from those of indigestion from other causes, except that the symptoms did not disappear rapidly with simple treatment. Dr. Spriggs detailed the main symptoms of carcinoma in the order of their appearance: discomfort in the abdomen apart from food, loss of appetite, pain after food, heartburn, flatulence, vomiting, regurgitation of mucus, weakness, loss of weight, dysphagia, and tumour. In a few cases hæmatemesis was the first indication of the disease. A palpable tumour was always a late sign; as a rule it meant that the growth was inoperable, but not always. In any case in which the possibility of malignant disease of the stomach was suspected all the methods of diagnosis should be employed; the fæces should be examined for occult blood, the gastric juice should be tested, and X rays should be used. The earliest objective sign of cancer was probably local arrest of the peristaltic wave of the stomach as shown by X rays.

Prof. H. FINSTERER (Vienna) said that as a cancer of the stomach can be cured only by an operation, an operation should always be attempted as long as there are no signs of metastases, such as ascites and jaundice. The extent of the cancer largely influenced the operative results. If the disease was limited to the stomach and only the stomach had to be resected, the immediate results were relatively good, for the operative mortality in his cases was only 5 per cent. Part of this good result was due to the use of local anæsthesia in elderly patients. If owing to involvement parts of the pancreas, liver, or colon had to be resected the operation mortality was far higher, over 37 per cent.; yet even in these patients resection was justifiable, for some had survived for 5 to 13 years. To get good permanent results the operation must be very radical, the whole lymphatic area must be removed, even if the glands were not apparently diseased. The whole of the greater and lesser omentum also must be removed. In 18·5 per cent. of his cases the cancer had developed in a simple ulcer.

Prof. RAFFAELE BASTIANELLI (Rome) reviewed his personal experience of 543 cases. The mortality of 239 resections was 28 per cent.; of 176 gastro-enterostomies, 21·5 per cent.; and of 118 explorations, 15 per cent. The mortality figures of any surgeon depended largely on the sort of case he would undertake to operate upon. Prof. Bastianelli's guiding principle was to remove the stomach as often as the anatomical conditions would allow and as extensively as possible. A great part of the operative mortality was due to thoracic complications. For several years he had employed local anæsthesia in gastric operations, giving a general anæsthetic in addition only where necessary. He favoured a Polya Reichel technique. A study of the recurrences was of importance in determining the extent of an operative technique, and a general routine ought to be adopted in all advanced cases. He did not think that the ovaries are affected from stomach cancer by cells dropping on to their surface, but that the invasion occurs from the hilus by lymphatic spread. Surgical technique had now reached a very high level, but it could not be expected that more than 7 per cent. of patients with stomach cancer seeking advice would be likely to be cured. It was therefore essential to study precancerous lesions, to use preventive surgery, and to recognise the earliest symptoms of cancer.

Prof. M. J. STEWART (Leeds) pointed out that it is generally possible to decide whether a cancer is arising from an ulcer. In an ulcer of the stomach there is a definite destruction of the muscular coat with a turning up of the ends of the bundles of fibres. In 239 cases of cancer of the stomach there were 15 per cent. in which the growth had certainly started from a simple ulcer. He showed some striking slides in which cancer of the stomach was associated with a large number of gastric polypi.

Mr. A. J. WALTON (London) stated that there is no evidence that gastric cancer is increasing; in fact, in his own practice, it is becoming a less frequent disease, and this fact he was inclined to attribute to the fact that many patients have been saved from carcinoma by having their simple gastric ulcers treated surgically. As to the results of operation, between 1913 and 1924 he had performed 62 partial gastrectomies; of these 3 could not be traced. Subsequently, 55 had died of recurrence and 4 were still alive. Of these 4 one had lived 15 years, one 12 years, one 10 years, and one 7 years. To better the results it was, in the first place, essential that a correct diagnosis be made earlier; in the second place, since a certain number of cases arise in simple ulcers, these should be treated surgically if they did not respond readily to medical treatment.

Prof. D. P. D. WILKIE (Edinburgh) mentioned that in over 44 per cent. of all cases of cancer the stomach is affected. It was an insidious disease and early diagnosis was essential if any real benefit was to be derived from operation. Among 675 cases admitted into the Royal Infirmary, Edinburgh, only in 60 cases was a radical operation possible. Examination by X rays after a barium meal was by far the most valuable form of evidence, though it was not absolutely infallible, for in some malignant cases a diagnosis of a simple ulcer has been made. Since there was a chance of error in all available diagnostic methods the question of an exploratory incision should always arise where doubt existed. It was advisable that everyone should be submitted to periodical medical examination; for then in many cases malignant disease would be recognised at a stage when operation would be most valuable. Treatment by radiation offered less hope in this than in almost any other form of cancer.

Dr. MACCARTY quoted the statistics from the Mayo Clinic. Of 1680 cases of operation on the stomach 869 were for chronic ulcer and the remainder were for cancer. The operation mortality of the cancer cases was 9·5 per cent.

Mr. HERBERT W. CARSON (London) said that the cause of the low percentage of cancers of the stomach suitable for operation was that patients came to the surgeon at too late a stage. Middle-aged or old men should not be treated for indigestion until cancer had been ruled out. The earliest sign was generally loss of appetite, followed by loss of energy and wasting. If at an operation the complete removal of the disease was impossible, benefit and increase of comfort would often follow a jejunostomy.

Sir BERKELEY MOYNIHAN, in reply, urged that diagnostic methods should be cheapened, and this he regarded as the duty of the Government. It would pay insurance companies to charge reduced premiums to a person who could at intervals of six months produce a certificate that he had undergone a thorough examination by a competent doctor. Cancer of the stomach, as cancer elsewhere, is a local disease, which should be recognised and removed at the earliest possible moment.

DIAGNOSTIC METHODS IN RELATION TO CANCER.

Sir WILLIAM HALE-WHITE being in the chair. Sir THOMAS HORDER opened the discussion on this subject. Since, he said, we believe the disease to be a local condition in the first stages, early diagnosis was imperative; a difficulty of paramount importance was introduced, however, by its local character, since it deprived us of serological and analogous methods dependent on generalised effects. Diagnosis, he went on, presented three stages: First, a local change with no general disturbance, the curable stage; secondly, dysfunction of the part with anatomical change; thirdly, the stage of cachexia. In early diagnosis he placed great value on the significance of symptoms—he could hardly emphasise sufficiently the importance of dyspeptic symptoms in a patient previously perfectly well; he thought the school which taught that cancer intervened on chronic dyspepsia and other conditions were entirely wrong; in the majority of patients the disease arose in healthy organs. He pleaded for simplicity of technique in laparotomies; patients might then be more willing to submit to them. All additional aids should be employed when suspicious symptoms arise—radiology, biopsy, serology, hæmatology, and biochemistry.

Dr. T. Izod Bennett (London) said that treatment was a pious hope for the future, early diagnosis was the problem for to-day. Prognosis in cancer of the stomach was at present far worse than cancer in any other situation since early symptoms were so insidious and access to the organ was difficult. There were, he said, three diagnostic procedures of great value. X ray photography was the method of first choice, a loss of mobility appeared before a filling defect, also the presence of an ulcer in a patient whose history was of brief duration should raise suspicion of malignancy. He gave no support to the theory that malignancy supervened on chronic ulceration. Gastric analysis, he said, when carefully performed, yielded reliable diagnosis in about 90 per cent. of cases; signs were often most conspicuous in the fasting content. Lactic acid, when present, was said to establish the diagnosis beyond question. Finally, gastroscopy, he thought, was a method for the future, although at present disappointing. Serological tests would be unlikely, he thought, to diagnose cancer at a curable stage.

Dr. MacCarty (Mayo Clinic) said the dominant theme in America was "Bring your sores and lumps to the physician early." In his opinion no cancer was early if larger than ½ cm. in diameter. X ray examination by an expert would tell if there was a lesion in the stomach, and ulcers should be excised because diagnosis of malignancy could not be made. The speaker showed a chart illustrating stages in development of cancer from gastric ulcers, and said that 39 of 869 cases showed malignant change. Malignancy could be expected when the average diameter was 2·17 cm.

Prof. L. S. Dudgeon described his technique (published in the *British Journal of Surgery*, 1927) for making rapid wet-film examinations of neoplasms. He said that autolysed tissues and fixed tissues were unsuitable for investigation. Considerable skill was necessary, but he could now diagnose correctly in 98 per cent. of cases.

Prof. Lewis (Liverpool) said that normal blood serum acting on pancreatic lipase augmented its lipolytic power. In certain conditions, including cancer, the lipolytic augmentation was reduced. He showed tables to prove that in cases treated with lead clinical deterioration went hand in hand with a decreasing lipolytic augmentation, whilst improvement accompanied a rise.

Prof. Blair Bell said that while the lipase coenzyme activity of the serum was not a specific diagnostic method, it was of great value in assessing the progress or retrogression of malignant disease.

Prof. Ascoli (Catania) said he saw the immediate future of sero-diagnosis of cancer in the methodical research in non-specific reactions.

Dr. H. J. B. Fry (London) described a flocculation reaction in routine use at the Cancer Hospital for the sero-diagnosis of malignant disease. In 1550 malignant and control cases correct results were obtained in 73·3 per cent. The reaction appeared to depend on products of cellular or tissue disintegration.

Dr. J. Braxton Hicks (London) described work he and Dr. Hocking had undertaken to evolve a complement-fixation test for cancer. They were, he said, prepared from the beginning for negative results, since the fixed tissues of a part seemed so indifferent to the intrusion of cancer cells; their work was further complicated by deterioration of the antigens. The results proved inconclusive.

Dr. S. Melville (London) talked on diagnosis of intrathoracic neoplasm by X rays. The radiologist sees not the growth but the result of stenosis of the bronchus; when less commonly, the growth invaded the lung, the diagnosis was much more difficult. Two great aids in diagnosis, he said, were production of artificial pneumothorax and injection of lipiodol. In illustration he showed skiagrams on the epidiascope.

Prof. E. C. Dodds (London) said that he and his assistants had worked for three years testing methods for diagnosing malignant disease from a study of the composition and behaviour of the blood. In particular he had investigated the Abderhalden, the Shaw-Mackenzie, and the Ringold methods; all these investigations proved the methods quite unsuitable for the diagnosis of malignant disease.

Dr. K. Itchikawa (Japan) showed a chart illustrating the modifying effects of varying amounts of albumin and globulin in Botelho's serum reaction for early diagnosis of cancer; in certain cases it appeared possible for it to give a positive reaction where no cancer was present.

The Chairman, in closing the discussion, said that in advocating laparotomy, obvious risks must not be forgotten such as mortality from anæsthetics, adhesions, and the bad effects on neurasthenic patients. The physician should therefore have strong grounds on which to base a recommendation for operation. The results of sero-diagnosis were, he thought, disheartening; the most reliable test seemed to be the biopsy test. He referred to the great discordance of opinion as to the frequency of cancer of the stomach in regard to gastric ulcer, and suggested that it was probably more common in America than in other countries; in his experience it was a very rare occurrence. He said that in his opinion the test-meal was of great value in diagnosis, particularly ferment activity and the absence of active hydrochloric acid. He considered that the only hope of cure lay in early diagnosis.

On the same day the Section of Radiology, under the chairmanship of Dr. Robert Knox, discussed the

Effects of Radium and X Rays on Circulatory Systems, with Special Reference to Malignant Growths.

Prof. F. C. Wood (Columbia) said that the effect of radiations, electric currents, and even excessive heat and cold upon the blood-vessels was to cause a thickening of their walls. The vascular changes following exposure to radium and X rays were especially clear-cut, and probably played a part in the therapy of tumours and in the chronicity of ulcers following over-dosage. Twenty-four hours after heavy exposure the intimal endothelium of small arteries and the muscular coat were swollen, and as the process became chronic the œdema disappeared, the endothelium proliferated, and the vessel might be closed. Veins showed only a slight thickening of walls. The importance of this change lay in the reduction of the blood-supply to the part, consequent on the arterial thickening, and this was a factor in the arrest of a tumour. Lymph vessels, at an early stage of irradiation, showed no alteration. Later some dilatation might be observed, but the vessels did not become closed. No therapeutic doses of irradiation were capable of closing lymphatics.

Dr. A. Lacassagne (Paris) asked what part was played in the regression of cancerous tissues by circulatory changes following irradiation, and said he thought it was largely a question of starvation due to restricted blood-supply. As to the lymphatic vessels, knowledge as to what occurred in these following the use of rays lacked precision, though it was clear that in cancer-sterilising doses irradiation might disturb the lymphatic circulation, at least in certain regions of the skin. To kill the cancer cells—a necessary condition for the cure of a malignant neoplasm—it was necessary that the radiant energy should impinge directly on to them. Sclerosis of the dermis, and consequent obliteration of the lymphatic circulation might sometimes retard and localise the growth of certain cutaneous cancers.

Prof. H. **Holfelder** (Frankfort-on-Maine) said it was recognised that in dealing with cancers by radiotherapy the object was to cause the degree of reaction which normal tissues could just tolerate without sustaining permanent damage. An excessive dose of X rays led to a more or less complete obstruction of lymphatic and smaller blood-vessels, especially the capillaries, thus obstructing nutrition to healthy tissue. This must always be avoided. For even a lethal dose of radiation to be effective on cancer, the help of the connective tissue was needed, and this complex intracellular metabolism was conditioned mostly by the blood and lymph flow. There was always an interval after irradiating a growth before any sign of reduction was observable.

Mr. **Clifford Morson**, speaking as a surgeon who practised radiology, said that a large dose of radium caused extravasation of blood, whereas a smaller dose produced obliteration of the blood-vessels, without rupturing their walls. Malignant growth of a blood-vessel (endothelioma) could be destroyed by irradiation. In the treatment of malignant disease by irradiation it was important to remember that the greater the vascularity of the organ in which the tumour was growing, the better the results from such treatment; good examples were growths of tongue and uterus. The cutting off of the blood-supply had three advantages: immediate cessation of the hæmorrhage, deprivation of nourishment to the tumour, and the retention of any substance which exerted secondary radiation.

Dr. **Douglas Webster** spoke of metabolic changes in the blood. He said it was agreed that huge doses of irradiation were needed to damage the cancer cells directly, and it was necessary to take into consideration also the connective tissue stroma of the growth, and the blood and lymphatic distribution.

Prof. H. **Holthusen** (Hamburg) pointed out that as irradiation could alter the sensitiveness of the skin the erythema following deep irradiation was not always a safe indicator as to the dosage being applied.

Dr. F. T. **Burkitt** referred to the direct action on blood produced by pure gamma rays.

Dr. W. **Levitt** spoke of a series of cured cancer cases which he had treated by intensive X ray radiation, in all of which there was, during treatment, a rapid decrease in the lymphocyte count.

The **Chairman** thought that until quite recently the indirect effect of irradiation on tumours had not received adequate attention, but he had now been able to organise research on this aspect, in the hope that guidance for treatment would emerge. Already practical results had been achieved. His own view was that a drop in the lymphocyte count was an indication to go slowly with the irradiation. He was not sure that the profession even yet realised the damage which might be caused by injudicious exposures.

GEOGRAPHICAL AND RACIAL PREVALENCE OF CANCER.

At the Section of Statistics and Public Health the chairman, Lieut.-Colonel F. E. **Fremantle**, M.P., in his opening remarks, emphasised the value of the study of public statistics. They were often extremely suggestive. At the same time it was most important to guard against a wrong use of statistics, for they easily lent themselves to false representation.

Prof. **Major Greenwood** (London) sought to define the problems at issue and give some account of the data needed for their solution. In comparing the mortality of cancer in different races great differences were found, but it had to be decided: first, whether these differences were merely the outcome of better or worse systems of recording; and, secondly, if not, whether they were due to habits of life, climate, and other environmental factors, rather than to differences in racial character. These questions had never been satisfactorily answered.

The majority of those who had studied official vital statistics were satisfied that the mass comparison of national rates of mortality from cancer was at present of little value. However, the comparison made by the Health Organisation of the League of Nations between cancer of the breast and uterus in the female populations of England and Wales, Italy, and the Netherlands showed clearly that death from cancer of these sites was far more common in England, whereas gastro-intestinal cancer was more prevalent in the other countries. No explanation had been found for this. The total mortality from cancer in these countries was about the same.

The fact that this national contrast was specific and not general suggested that its origin was likely to be environmental. For instance, they would expect that kangri cancer would occur with similar frequency in all races who adopted the particular practice which was the exciting cause, although this expectation might be falsified by racial variations in responsiveness. When it was a question of pathological change in sexual organs they might speculate as to whether the explanation might not be in some difference in the sexual practices of the peoples in question, a subject of which little was known. The conclusion drawn was that they had not sufficient data nor sufficiently powerful methods of statistical analysis to solve these problems. With the object of adding to these data he desired to refer briefly to the regional distribution of cancer in England and Wales.

Cancer was regionally less variable than the non-tuberculous respiratory diseases; in fact, its local variability was not great. Unfortunately the existing English data were quite inadequate for the racial characterisation of different parts of the country. If the sharpest contrast from the racial point of view was made which the data permitted—viz., between the Welsh cities and those of the east of England—it was found that for cancer as a whole the two groups gave practically identical rates, although for other causes of death there was a large difference.

The scanty collection of data available served to confirm the impression that the geographical and racial factors of variability were of less importance in cancer than in other great causes of mortality. A point of interest which emerged from the League of Nations' study was that whereas mortality from sites other than uterus or breast was correlated with mortality from non-cancerous conditions, no reliable correlation could be discovered between mortality from cancer of these sites and mortality from non-cancerous conditions. This complicated the problem and was an additional argument for his contention that we needed more facts before we could frame hypotheses.

In the absence of Prof. A. **Niceforo** (Naples) and Prof. E. **Pittard** their communications were summarised by Prof. **Greenwood**.

Prof. **Niceforo** divided Europeans into the following races or anthropological types: *Homo nordicus, H. alpinus, H. mediterraneus, H. orientalis, H. dinaricus.* Italy was peopled by representatives of the types alpinus and dinaricus in the north, alpinus or mediterraneus in the centre, and mediterraneus in the south and islands. He found statistical correlation between the presence of the Mediterranean type of short stature, dark, dolichomorphic cranium, and the lower rate of cancer incidence, while the presence of the brachymorphic alpinus and dinaricus was associated with a higher cancer-rate. But he doubted whether it was race or race alone which influenced the cancer mortality, for in some provinces of northern Italy inhabited by populations of the Mediterranean type the cancer incidence was as high as that of other northern provinces. The author then considered racial types and cancer incidence in other European countries. He could draw no conclusions from the facts available, and was of opinion that the problem was so complicated that even where excellent material was available the statistical method by itself could not suffice. He proposed a new way of studying the question by direct examination of some thousands of cancer patients. It could then be seen whether certain morphological characters were more frequent in cancer patients or not. It would be easier to carry out than the other and might lead to more certain conclusions.

Prof. Eugene Pittard (Geneva) discussed the question of race. In Europe the Nordic race appeared to be most affected by cancer, the Mediterranean race least. He compared the rates of mortality from cancer in Sardinia, Sicily, and Malta. They were respectively 32·4, 41·1, and 48·2. Sicily showed a higher rate than Sardinia because its racial condition was less homogeneous. The rate in Malta was explained by the presence of a colony of Nordic Britons. London had a much higher cancer mortality than New York. New York had a heterogeneous population; London was mainly Nordic.

Dr. M. Sourasky (London) read a paper on the Incidence of Cancer among Jews and the Problem of a Specific Racial Factor in Cancer. In studying cancer among Jews account must be taken not only of the comparative incidence of cancer mortality, but also that of various organs separately. There was no truth whatever in the suggestion that Jews were immune from cancer, nor were they specially prone to it. The speaker showed figures from six European capitals in support of his statement. Speaking generally the variation was geographical, not racial.

But when the incidence of cancer of the various organs was examined it was seen that cancer of the uterus, penis, and buccal cavity was less among Jews, whilst that of the gastro-intestinal tract showed a greater frequency. Cancer of the tongue was about half as frequent in Jews as in the non-Jewish population. This could be accounted for by the lower incidence of syphilis, and therefore of chronic superficial glossitis amongst them. Their immunity to penile cancer was explained by circumcision. A similar immunity was found among the Mohammedan Indians, who practised circumcision, while the Hindoos of the same race who did not were prone to be attacked. The figures for carcinoma of the breast varied, being sometimes lower, sometimes a little higher than those for the rest of the population. In London the mortality from breast cancer among the poorer Jews was decidedly lower (60·9 per cent.) and that of the richer somewhat higher (103·7 per cent.), compared to England and Wales generally (100 per cent.). The explanation here was simply a matter of social status; among the richer Jews were more unmarried women, later marriages, and a lower birth-rate, all of which factors favoured breast cancer.

The remarkably low incidence of uterine cancer (one-third to one-half the number occurring in the rest of the population) appeared to be due to the observance of the Mosaic ritual laws by the mass of Jewish women. Their main provisions were the prohibition of coitus at certain times and the imposition of frequent ritual baths. The practice of this code produced a high degree of sexual cleanliness and restricted cohabitation at times when rest was probably beneficial. Some continental authorities held that while carcinoma of the cervix was a disease of married life pregnancy was not an essential factor. This view was not widely accepted, but it was clear that married life was the usual precursor of cancer of the cervix. A well-regulated sex life might therefore be a favourable factor in the avoidance of disease. In any case, obedience to the Mosaic code resulted in a highly satisfactory sexual hygiene.

With regard to the high mortality among Jews from gastro-intestinal cancer no ætiological factor could at present be brought forward. Racial predisposition had no evidence in its favour. It could only be suggested that the well-known tendency of Jews towards metabolic disturbances should be remembered in this connexion.

Dr. Percy Stocks (London) read a paper on the evidence for a regional distribution of cancer prevalence in England and Wales. He concluded that after correction for sex, age selection, urbanisation, and migrational selection the mean cancer indices of the county areas grouped themselves into definite regions of high and low prevalence, showing that geographical influences were in some way concerned. The large towns showed wide differences which could not be explained by their age or social distributions, and their rates tended to be generally consistent with those in the surrounding country.

Dr. Matthew Young (London) was unable to be present. His studies of cancer mortality and the distribution of racial types in Scotland suggested that if any real association existed it was in inverse ratio to that shown in other parts of Europe, for the greater the proportion of the Nordic type in the population the less the cancer mortality.

Dr. R. M. F. Picken (Cardiff), in discussing Dr. Stocks's paper, pointed out the danger of drawing conclusions when all the factors were not understood. South Wales was racially no more Welsh than the English counties around North Wales. Probably Liverpool and Lancashire had more Welsh stock than the Welsh counties.

Commander Gibbon showed statistics of the incidence of cancer in the Navy and in the native labour force at Singapore. The figures of incidence of gastro-intestinal cancer paralleled closely those of the incidence of disturbances of the digestive system in general.

The second discussion on the same morning centred round

Public Action in Regard to Cancer.

The opening address by Sir George Buchanan (Ministry of Health) will be found elsewhere in this issue.

Prof. J. Maisin (Louvain) considered that the most effective way of prosecuting the campaign of cancer in any country was to provide a number of anticancer stations. The stations should be of two kinds: primary fully equipped stations and secondary stations. Each station should be under the charge of a director, who should be a laboratory man with good clinical knowledge or a physician, because the choice of a surgeon or radiologist might tend to a one-sided view of the scope of research or a consequent suppression of initiative in some directions. The station must be equipped like a large modern hospital and must have first-class specialists in all branches of medicine. Supervision of patients who have undergone treatment must also be provided for and a complete system of records kept up. Research centres were a necessary part of each station. Centres of instruction for young practitioners were absolutely indispensable and courses of instruction in the early diagnosis of cancer should be made compulsory. Lectures, popular instructions, and the distribution of pamphlets should not be neglected, but they were of secondary value and should be used with prudence so as not to provoke carcinophobia. The duty and interest of the public was to assist by every means at their disposal in the realisation of such an undertaking.

Dr. G. A. Soper (New York) described the work of the American Society for the Control of Cancer. This Society had sought to instruct the public concerning cancer by means of pamphlets, posters, lectures, moving pictures, radio, magazine, and newspaper articles, and finally by "cancer weeks." The latter especially appeared to arouse great enthusiasm and led to thousands of people coming up to be examined in the temporary clinics held, many cases of cancer being thereby discovered.

Dr. Stanley P. Reimann (Philadelphia) had made a careful statistical study of the influence of the educational campaign on the interval between discovery and consultation in mammary carcinoma. During the years from 1900 to 1927 inclusive there had been a steady decrease in the time interval between the discovery of carcinoma by the patient and consultation with the physician or surgeon. There had been no inflection in the curve to indicate that the educational campaign begun in 1914 had had any effect. The improvement during the first 14 years when there was no educational propaganda was just as great as during the last 14 years. The speaker liked to think the steady progress was due to better training of physicians.

Sir **John Robertson** (Birmingham) discussed the cancer problem from the point of view of a medical officer of health. In Birmingham cancer mortality was on the increase, especially among males. Fifty years ago the incidence was one male for every two females; now it was one male for every one female. The type of district made no difference. In those who had died of carcinoma of the breast the average time between the patient noticing a lump and applying to a doctor was 10·2 months. He did not advocate compulsory notification because of the difficulty of offering suitable treatment to all cases. The public should be educated as was done for tuberculosis.

Dr. **Veitch Clark** (Manchester) advocated the public control of cancer as the immediate practical way of dealing with the disease. He was not in favour of cancer clinics. Quack treatment of cancer should be made illegal. It was necessary to clear the public mind of misconceptions concerning cancer. He described the work now being done in Manchester.

Mr. **Arthur Cooke** (Cambridge) proposed the establishment of clinics where routine breast examinations of the whole female population could be made once a year. In a population of 100,000 there should be something under 100 cases for discovery annually.

Prof. **Fichera** (Milan) described the Vittorio Emanuele III. Cancer Institute of Milan, opened on May 1st of this year.

Dr. **L. M. McKillop** (Queensland) gave statistics on the incidence of cancer in Australia and described the Queensland Cancer Campaign.

Dr. **Mortloch Brown** called attention to the needs of rural districts. She criticised the use of the term "pre-cancerous."

The **Chairman** said there was one thing he wished to impress upon his audience—the duty of refuting statements made on untenable statistics. In the last few months a campaign had been going on amongst the medical profession that certain forms of food produced cancer. An eminent surgeon was even devoting his life to persuading the public that cancer was due to eating meat. There was nothing whatever in statistics to support this. The statement that cancer of the intestine was unknown in India had been entirely refuted. He commented on Dr. Sourasky's remarkable paper and thought that the Mosaic law could give them points in prevention of cancer. Dr. Reimann's paper showed the failure of flamboyant propaganda and the value of steady educational progress. He himself advocated medical inspection every five years after the age of 40. There was no definite message from this Conference. They could not show much to be done on communal lines at present, but they were going forward. They must look to the laboratory workers, especially to pathology, for help. Meanwhile attention to general hygiene had effect in curtailing the ravages of cancer.

THE CANCER HOSPITAL DINNER.

At the invitation of the medical and surgical staff of the Cancer Hospital, about 120 guests sat down to dinner at the Langham Hotel on Thursday, July 19th, when Mr. W. Ernest Miles, senior surgeon to the hospital, presided over a distinguished and representative international gathering. After the loyal toast Sir Berkeley Moynihan proposed "The Cancer Hospital," describing surgery and research as the two arms of medicine at the present day, full use being made of both at the ideal hospital, of which the Cancer Hospital was a notable example. Mr. Miles. in replying, referred to the inspiration which the late Sir Charles Ryall had been to all his colleagues on the staff. Mr. Miles then proposed "The Overseas Visitors," whose achievements he described as beacon lights along the dark road of cancer research. Surgery, he said, it was now admitted, no longer stood alone in the treatment of cancer; radiology stood alongside it, and the wise surgeon would be an expert radiologist, or the wise radiologist an expert surgeon, if indeed, as would be better, the two did not coöperate. The veteran Prof. J. Rotgans, of Amsterdam, and Dr. J. B. Murphy, of the Rockefeller Institute, New York, replied for the visitors, the latter giving the results of his search into the early documents of the Cancer Hospital, which was, as he had discovered, "founded for the relief of a disease for which science has as yet afforded so little help." He remarked on the courage of calling it frankly a "cancer" hospital (which would be impossible in the United States), thus helping to remove that terrific dread and horror which was so potent a force in aiding the spread of cancer in a community. Sir Charles Gordon-Watson proposed "The Chairman" in a neat little speech. Amongst those present were Prof. R. Bastianelli, Prof. J. Ewing, Prof. C. Regaud, Prof. H. Finsterer, Sir John Bland-Sutton, Sir F. Gowland Hopkins, Sir Thomas Horder, and Sir Richard Garton.

UNITED STATES OF AMERICA.

(From an Occasional Correspondent.)

Rabies in Chicago.

Prof. E. O. Jordan, of the University of Chicago, and Dr. E. E. Irons, dean of Rush Medical College, representing the Chicago Institute of Medicine, have issued a public statement of the growing menace of rabies in that city. During the first five months of this year 561 dogs' heads were found rabid out of 704 examined in the laboratory of the health department. In the same period for 1927 only 11 heads were found positive out of 56 sent for examination. In May of this year there were seven times as many positive diagnoses of canine rabies as in the whole of the year 1926. In the last 12 months 1046 persons known to have been bitten by rabid dogs have been given the Pasteur treatment; this figure, however, does not include an unknown number treated by private physicians. There were no human deaths from rabies from 1919 to August, 1927, in the city, but since that time no less than 19 deaths have been reported. Muzzling is called for and the prompt destruction of all stray unmuzzled animals. One may be sure that if Mayor Thompson had not removed from office the competent commissioners of health whom he found in charge of the department, it would not have been necessary for the Institute of Medicine to issue this urgent warning.

Key Catalogue of Insects.

The fourth of a series of key catalogues on medical zoology recently issued by the United States Public Health Service, is entitled Key Catalogue of Insects of Importance in Public Health.[1] It has been prepared by Prof. C. W. Stiles, of the Public Health Service, and Dr. Albert Hassall, of the Bureau of Animal Industry. Accurate classification and cross-indexing make the index exceedingly valuable to all interested in medical entomology. For example, a dermatologist in search of the caterpillars which cause urticaria looks up this word in the introduction under Dermatology, and finds cross-references to 40 different genera of moths and butterflies, the larval stages of which cause urticaria in man.

Risks of Tourist Camps.

A menace to vacationists in this country is the rapidly growing number of tourists' "camps." These camps vary in their conveniences from a strip of untidy earth on which motorists may put up their tents and cook a picnic meal, to small colonies of comfortably furnished wooden or stucco cottages with numerous modern conveniences at hand, including shower-baths and an electric laundry. Some of the State health departments, as, for example, Indiana, have become awake to the need of inspecting such wayside camps, for insanitary privies and contaminated water-supplies are not at all uncommon among them. The Indiana health department provides a certificate of approval, which is to be displayed prominently, and also undertakes to close camps which are not found satisfactory, or which do not become satisfactory after reasonable notice has been given.

MEDICINE AND THE LAW.

Parents' Responsibility for Operations on Children.

IN his last annual report the medical officer of health for Cumberland dwelt upon recent proceedings against parents who declined to submit their children to operations for the removal of adenoids and tonsils. These cases, under Section 12 of the Children Act, alleging neglect of a child by reason of failure to provide adequate medical or surgical aid, naturally excite controversy, and the local newspapers have published letters in which the action of the parents is stoutly defended. The medical officer, it is said, is merely balancing two remote contingencies. A child is unlikely to die under an operation for removing adenoids: on the other hand, it is unlikely to die or to suffer serious damage if no such operation occurs. Many people, it is argued, live fairly happy and comfortable lives, as life goes in this ill-constructed world, with tonsils and adenoids complete. It is a choice between two remote possibilities—death or serious injury under operation on the one hand, and grave injury to comfort, through throat affections, on the other. Positive certainty of considerable pain and the disagreeable consciousness of mutilation attach to one choice alone. Such are the comments which proceedings under Section 12 evoke. They resemble the comments on other occasions—in connexion with vaccination, for example. There is the same association with strong family feeling, love of liberty, distaste for operations, and dislike of official interference. Parents, fond of a child, naturally resent the allegation of criminal neglect which Section 12 imputes.

While it is impossible to ignore these hostile views, it is too late in the day to put them forward in a court of law. The case of Oakey v. Jackson, in 1914, left no doubt whatever of the parents' duty. A girl of 13 was suffering from adenoids which were causing mental dullness, impaired breathing, deafness, and some anæmia; the only possible remedy was a surgical operation for removal of the adenoids. Failure to permit that remedy was alleged to be causing "unnecessary suffering or injury to health" within Section 12. The father and mother thought an operation unnecessary; they did not believe in operations, and they refused to allow the child to go to the infirmary where the operation could be performed. On their behalf it was argued that the Act never intended to make surgical operation compulsory; the performance of the operation and the administration of the anæsthetic must involve some measure of risk to life; parents were justified in refusing to take the risk, and such refusal was not a failure to provide adequate medical aid. The justices agreed and declined to convict, but the King's Bench Division remitted the case to them for reconsideration. Darling J. quoted the dictum of Lord Russell of Killowen C.J. in Reg. v. Senior: "neglect is the want of reasonable care—that is, the omission of such steps as a reasonable parent would take, such as are usually taken in the ordinary experience of mankind." Applying that opinion to Jackson's case, Darling J., with an unusual disregard for the canons of judicial ignorance, remarked that it was not necessary to know much about surgery to know that the operation for the removal of adenoids was very common in the case of children, and that a failure to perform the operation might result in danger to life if the child should ever happen to be attacked with illness. The parent, he continued, was under a legal liability to allow the operation if the refusal to do so was in the circumstances a failure to provide adequate medical aid. It was a question of fact in each case, and the justices might very properly have convicted Jackson. The justices, it appears, cannot evade the responsibility of dealing with the facts. In a case reported in the *Times* of May 21st, 1912, the justices convicted a father, under Section 12, of neglect to provide medical aid in the form of an operation for cleft palate. The High Court then refused to make absolute a rule *nisi* for *certiorari*, the question being simply one of fact for the justices. The latter have to consider the nature of the operation and the reasonableness of the refusal. It is all very well to argue that there is merely a choice between two remote contingencies, and that the parents, rather than the medical officer, should have the right to choose. The material for the decision must mainly be a matter of medical evidence. One thing to be taken into consideration by the justices, said Avory J. in Oakey v. Jackson, is whether the person who advises the operation is a qualified medical practitioner or merely some irresponsible person.

So stands the law, and arguments and comments must not ignore the law. In the last resort, of course, a parent might say, "I do not recognise the law and, sooner than allow an operation upon my child, I will go to prison." Conscientious objection may be a rule of conduct; it is not a legal defence. Before the Children Act was passed in 1908, there was an earlier statute containing something akin to Section 12. Under this earlier Act Robert Downes was prosecuted in 1875. His child had been wasting for some nine months from chronic inflammation of the lungs, and then died. The father belonged to a sect which never called in medical advice but called in the elders of their church to pray over sick persons. The Court held that, whatever doubts might exist as to a duty at common law to provide adequate medical aid, the statute left no doubt whatever. The statute, said Baron Bramwell, imposed an absolute duty upon parents, whatever their conscientious scruples might be: "the prisoner wilfully (not maliciously, but intentionally) disobeyed the law and the death ensued in consequence." Those who disagree to-day with the positive duty imposed upon parents by Section 12 of the Children Act are perfectly entitled to demand that the law be changed. It is doubtful if such an agitation will commend itself to an electorate to which a large feminine contingent has lately been added. Meanwhile, medical officers of health are equally entitled to draw attention to the existing law, and, in this respect as in others, to seek to educate the public in all health matters.

DONATIONS AND BEQUESTS.—Mr. Walter Kerr Fernie, of Thornton Hough, Cheshire, and of Liverpool, besides other bequests, left £1000 to the executors for such charitable institutions or objects and in such proportions as they may think fit, and £500 each to the Liverpool Royal Infirmary; the David Lewis Northern Hospital, Liverpool; the Royal Southern Hospital, Liverpool; the Stanley Hospital, Liverpool; the Royal Liverpool Hospital for Children; and the Neston Cottage Hospital.—Miss Mary Turnbull, of Nottingham, left £1000 to Nottingham General Hospital for the purposes of the superannuation fund connected therewith.—Mrs. Elizabeth Jane Reddaway, of Southport, among other bequests, left £500 each to St. Mary's Hospital for Women and Children, Manchester, to Henshaws Institute for the Blind, to the Northern Counties Hospital for Incurables, to the Hospital for Consumption and Diseases of the Chest, Manchester, to the Children's Hospital, Manchester, to the Christie Hospital, Chorlton-on-Medlock, to the Babies' Hospital, Slade-lane, Manchester, to the Manchester and Salford-street Children's Mission, and to St. Dunstan's Hostel.—Mr. Edward Masfen Arrowsmith, of Sydenham-park, left £500 to the Home and Infirmary for Sick Children, Lower Sydenham, S.E., and £500 to the Metropolitan Convalescent Institution (Seaside Branch).—Mr. Arthur Tyler, Oadby, Leicester, left £500 to the Leicester Royal Infirmary, £250 to the Leicester Guild of the Crippled Holiday Home, and £200 to the Leicester and Rutland Institution for the Blind.—Mrs. Elizabeth Wilson, North Shields, bequeathed £16,500 to the Tynemouth Jubilee Infirmary for additional buildings.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT CARDIFF.

REPRESENTATIVE MEETING: JULY 20TH-23RD.

THE annual Representative Meeting of the British Medical Association opened at the City Hall, Cardiff, on Friday, July 20th, with Dr. C. O. **HAWTHORNE** in the chair. The representatives were officially welcomed by the Lord Mayor.

Mr. A. H. Burgess, professor of clinical surgery in the Victoria University of Manchester, was elected President of the Association for 1929–30, and Dr. W. Harvey Smith, of Winnipeg, for 1930–31. Mr. R. G. Hogarth and Sir Robert Bolam were appointed Vice-Presidents, in recognition of their services as President and Chairman of Council respectively.

International Obligations.

Much discussion arose on a proposal that the B.M.A. should become a full member of the Association Professionelle Internationale des Médecins (A.P.I.M.), whose object it is to be an international union and bureau for the interchange of information and ideas on the social and political aspects of medical practice. The proposal had been rejected by the Council on the ground that membership would bring to the B.M.A. no advantages which would justify the annual subscription (£125) and the demands which would be made on the time of the medical secretary and his staff. The Council expressed its willingness at all times to furnish medical associations, national or international, with any information at its disposal, and several representatives said they thought this was sufficient evidence of the desire to help the profession in other countries. They pointed out that lack of funds already hampered expansion of the B.M.A.'s own work at home and that the expense of belonging to the A.P.I.M. might eventually reach £1000 a year, representing a very large capital sum. Medico-political problems, unlike those of science, were purely national, and must be settled nationally. The A.P.I.M. was young and had no prestige; to join at this stage would be a step in the dark. In answer to these objections it was argued that the purpose of joining might be to give rather than to receive. The new association could not thrive unless it was supported, and the B.M.A. had experience which would be really useful abroad. Membership of the A.P.I.M. involved no obligation to abide by decisions taken on the continent, nor did it commit the B.M.A. to expenditure beyond the subscription. The great need of the world was for international coöperation, and in point of fact there was much to be learnt from the ways in which other countries dealt with such problems as health insurance and the certification of the insane.

These last arguments carried the day, and the meeting instructed the Council to take the steps necessary to secure full membership of the A.P.I.M.

Radiotherapy by the Unqualified.

Mr. H. S. **SOUTTAR**, Chairman of the Science Committee, proposed:—

> That the Representative Body express the following opinion, namely, that in view of the risks to the public involved in the use of electricity and radiation as methods of treatment by untrained and unqualified persons it is to be desired (1) that suitable courses of training should be organised under medical direction for persons who wish to administer this form of treatment; (2) that persons who have satisfactorily followed such a course should be entitled to have their names entered on an approved roll; (3) that one of the conditions attached to admission to, and maintenance on, the approved roll should be abstention from the treatment of any patient except upon the responsibility and under the general supervision of a registered medical practitioner; and (4) that patients who require electrical or radiation treatment should be referred only to those persons whose names are on the approved roll.

He put forward the motion because it was undesirable that the public should be misled by the absurdly optimistic claims made by institutions providing treatment by ultra-violet rays and electricity. On the other hand, medical men wanted to be able to send their patients to places where suitable treatment of this kind could be skilfully given.

Dr. J. F. **WALKER** thought it unwise that the Association should set the seal of approval on any kind of unqualified practice. Could the line be drawn at chiropodists or herbalists?—Dr. H. B. **BRACKENBURY**, Chairman of Council, answered that there could be no objection to the establishment of a register containing the names of persons competent to do certain things, so long as they were prepared to do these things only under the supervision and direction of registered practitioners. The Association would never have opposed the registration of opticians had they not asserted the right to act as independent practitioners. The profession had to recognise at this time of day that there were craftsmen capable of doing things that medical men were not prepared to do for themselves.

The motion was carried by a large majority.

Proprietary Medicines and Secret Remedies.

The meeting approved a motion by Lancashire and Cheshire that the Council should "consider the advisability of resuming the investigation into the composition of secret remedies and the publication of the results." It was pointed out that a very large number of patients were misled by specious advertisements in the daily press, and that there was a constant stream of inquiries from doctors concerning the value of the preparations recommended. The Chairman of Council said that the matter had lately been considered, and it was thought that the cost might be prohibitive. The old publications could hardly be re-issued in their present form, but if they were revised it must be done ab initio.

The meeting was more impressed, however, by Dr. J. **D'EWART**'s reminder that the expense of publication. and even of actions at law, might easily be justified by what the Association would gain in the public esteem by work so obviously useful.

The New National Health Insurance Act.

Dr. H. G. **DAIN**, Chairman of the Insurance Acts Committee, said that the Minister of Health had informed the profession that there was little in the Insurance Bill that concerned their interests, but the few words affecting them had proved to be very important. The Act of 1924 had said that additional benefits should be administered by approved societies unless they were "in the nature of medical benefits." This clause was omitted from the new Act, and at the same time new additional benefits had been introduced. He proposed the following resolution:—

> That it is essential if the medical profession is to take part in the provision of additional (medical) treatment benefits under the National Health Insurance Acts that these, as in the case of statutory medical benefit, shall be administered in such fashion that the services of the medical profession, who elect to give advice and treatment in connexion therewith, shall not be under the control of any approved society or societies.

This was passed nem. con., and it was agreed that the principle ought to receive statutory recognition and definition.

Dr. **BRACKENBURY** said that the new Act gave the approved societies dangerously wider powers, but these could only be exercised with the Ministry of Health's approval. The profession preferred protection by legislation to protection by consultation. The new Act recognised two forms of additional benefit which had been separated by an unfortunate accident. The first was payment to a practitioner for treatment or advice outside the scope of any other additional benefit or of medical benefit, under a special scheme approved by the Minister for the purpose. The second was payment to approved charitable institutions (e.g., clinics) for similar forms of treatment. By law an approved society could adopt the second of these without adopting the first and thus the position of ecialists or consultants would obviously be preidiced. The Minister had promised to do the tmost in his power to dissuade an approved society om taking such action, but if societies proved efractory a situation might arise in which the ssociation would have to advise consultants and pecialists to take no part in a particular schemes.

Dr. E. R. FOTHERGILL (Brighton) expressed grave ears that specialists and consultants would lose ractice because the approved societies would tend o make arrangements with hospitals and institutions, nd after discussion the meeting unanimously ccepted his resolution instructing the Council to press n the Ministry "the necessity for the adoption or pproval of such regulations and schemes only as are n conformity with the appropriate fundamental principles," and to take such steps as may become necessary to unite the profession against accepting service under any other conditions.

Periodical Examination of Insured Persons.

Dr. ELIZABETH CASSON, for Windsor, drew attention to the value of regular medical examinations. The present race of adolescents, who had been inspected throughout their school lives, were, she said, far healthier than their predecessors, or than their contemporaries from places where such examination was not done. A discussion followed in which one speaker pointed out that regular *examination*—even without fee—would profit panel practitioners by keeping their patients away.

Mr. E. B. TURNER wished that approved societies could be induced to look at things in terms of health and efficiency instead of £. *s*. *d*., and the tendency of some representatives to discuss the financial aspect was discouraged by others who wished the meeting to express a general opinion for the information of the public. The following motion was carried by a large majority :—

> That in the opinion of the Representative Body the establishment of periodical medical and dental examination of all persons insured under the National Health Insurance Acts is urgently called for as an economic proposition, having regard to the return so to be obtained in health and productive efficiency; that every such insured person, when accepted as a patient on a doctor's panel, should be by that doctor medically examined and the result of that examination placed on record; that preliminary examination should apply also to dental examination, when that additional benefit is included and available under the National Health Insurance Acts.

Assistant Medical Officers in Mental Hospitals.

Dr. J. W. BONE, chairman of the Medico-Political Committee, brought forward recommendations on the payment of assistant medical officers in mental hospitals, as set out in the Council's report. These, he said, represented an attempt to bring the 1915 scale up to date, and were submitted for general approval. The report received a good deal of criticism, especially from Dr. PETER MACDONALD, who said that the proposals had not been discussed with the Royal Medico-Psychological Association, and might have an unfortunate effect on the present relations between the governing bodies of mental hospitals and their medical staffs. They would be taken as interference by an outside organisation and if they were applied might have the effect of levelling down salaries rather than levelling them up.

These views gained some support, but the Council succeeded in getting the general approval it asked for the proposals, on the understanding that the recommendations did not become part of the policy of the Association until there had been further negotiations with the bodies concerned.

Paying Centres for Infant Hygiene.

Dr. BONE reported that a deputation had waited upon the Council from the Association of Infant Welfare and Maternity Centres, and the Babies Club at Chelsea. The deputation said that there was a strong feeling that the mothers of the middle-class public should be able to get that guidance and instruction which is provided by the municipal and child welfare clinics for poorer mothers. Many private practitioners, it was considered, were unable or unwilling to give the kind of instruction required, and there were advantages in having the instruction given at a centre by a doctor who had given special attention to this branch of medical work, assisted by a fully trained nurse. The Council believed, said Dr. Bone, that the ideal was that mothers should be able to look with confidence to their own family doctor for the guidance required, but he thought it was no use to say that there ought to be no such centres as the one proposed. They already existed, and they would be set up in increasing numbers. The Council had been asked to say what were the right lines for their conduct and therefore put forward a resolution saying that the education of mothers was desirable, that there were already means by which it could be partially attained, that the further establishment of paying centres should be for the purpose of education and health propaganda and not for treatment, and that mothers preferring to avail themselves of the centres should do so with the knowledge of the family medical attendant.

The Council made several other recommendations on the subject, but opposition from representatives prevented their being considered.—Dr. FOTHERGILL and Mr. E. B. TURNER attacked the principle of countenancing clinics for people who could afford to have a doctor of their own.—Dr. J. W. JOHNSON said that young mothers were more and more seeking the aid of practitioners concerning the upbringing of children, and there was no excuse for lending aid to a misguided scheme of this kind.—Dr. E. A. STARLING deplored the extension of the "wave of clinics" from the poorer classes to the richer.—Dr. JOHN STEVENS thought that such a scheme must lead to overlapping and friction between clinics and practitioners, and Dr. A. B. MURRAY said that "if we're not fit to look after the children it's an end to private practice."

The Council's policy was supported by Mr. BISHOP HARMAN, Dr. DAIN, and Dr. BRACKENBURY.—Dr. CHRISTINE MURRELL suggested that not very long ago the proposal to establish infant welfare clinics for the poor had been looked at askance by the Representative Body; was there not a danger of opposing anything new, because it was new?

Dr. L. W. BATTEN spoke convincingly on the demerits of work at clinics, of which he claimed experience, and amid enthusiasm the meeting passed the following resolution, which represented the view of the Council in 1917 :—

> That while it fully appreciates the value of any educational work proposed to be undertaken at paying centres for middle-class mothers in the way of giving lectures on infant management, it does not approve of these centres providing consultations and advice in respect of mothers and young children belonging to classes of the community who are quite able to consult their own family doctor.

Maternal Mortality and Morbidity.

On a report brought forward by Sir EWEN MACLEAN, as chairman of a special committee, Dr. DAIN said he was specially impressed by the fact that better organisation would bring about a big reduction of puerperal mortality and morbidity. The report showed that three-quarters of the mortality could be done away with by measures of organisation alone, and the success being attained by certain workers in the slums of large cities ought to be available for the ordinary woman. The same view was reflected in speeches by Dr. JAMES YOUNG (Edinburgh) and Dr. R. C. BUIST (Dundee) who proposed that the Council's recommendations should be amended to include a resolution—preceding the others because of its importance—"that such immediate steps be taken as will ensure full and cordial coöperation between doctor and midwife." This was approved by the meeting, in conjunction with the following recommendations contained in the report :—

> (2) That steps should be taken to determine by further experimental research: (*a*) The factors which constitute and the conditions which vary resistance to disease, particu-

larly as regards pregnancy and the puerperium. (*b*) The best specific prophylactic measure to employ for the prevention of infection by *Streptococcus pyogenes*. (*c*) The length of time required to acquire such immunity and the degree and duration of such immunity. (*d*) The therapeutic value of specific as opposed to antiseptic measures in the treatment of *septicæmia caused by Streptococcus pyogenes.*

(3) That increased facilities should be provided for training medical students with special reference to antenatal work.

(4) That a condition of the payment of maternity benefit under the National Health Insurance Acts should be that the mother has had at least one antenatal examination by a qualified medical practitioner during her pregnancy.

(5) That members of the medical profesion should be encouraged to keep regular and careful records of their midwifery cases.

(6) That there is need for further provision of beds specially set aside for maternity cases in institutions. That every maternity home should provide for the complete isolation of septic cases.

(7) That the Association should consider the allocation of additional grants to promote research into the problems raised in this report, including especially the questions raised in the first recommendation of this report.

(8) That a Committee with adequate representation of practitioners be set up to formulate measures designed to bring about reduction in puerperal morbidity and mortality rates, to keep in touch with research work, and to assist divisions and branches of the Association in arranging for education and propaganda with regard to the value of antenatal service, the method of dealing with confinements, and the post-partum care of the mother and care of the infant.

Dr. BRACKENBURY, as a Direct Representative on the General Medical Council, said that the Council had been investigating allegations about the inadequate training of medical students in midwifery. The replies received from teaching institutions had almost all been satisfactory. and neither the public nor the profession need be under any anxiety. All medical students were having full opportunity for training in this sphere and were liable to a complete examination. There was no excuse for saying that the registered practitioner passing through the present régime was not fully trained for undertaking antenatal work, and there was no case for taking the matter out of the hands of the private practitioner.

In the consideration of this subject a certain amount of discussion arose between representatives who thought that the ideal midwifery service consisted of midwives assisted by specialists, and those who regarded the general practitioner as the proper person for the conduct of labour.

Payment for Ambulance Lectures.

Dr. PETER MACDONALD explained that at York the profession tried to carry out the B.M.A.'s policy that ambulance work is a matter of business and not of philanthropy. They had found, however, that elsewhere in the country medical men gave their services for nothing or for an honorarium. This was confirmed by other representatives who told of " blacklegging " by doctors. It was impossible, they said, to get the fee of one guinea for each lecture—a legitimate fee in view of the trouble involved in keeping up with the handbooks—so long as medical men were willing to accept presentation walking-sticks or railway vouchers instead of their rights. Dr. MILNER MOORE, who confessed, at the age of 88, that he had never previously addressed the Representative Body, strongly urged that the Association's policy should be maintained and observed, and this proved to be the opinion of the meeting as a whole.

Compulsion in the Treatment of Venereal Disease.

Dr. DAVID LEES, for Edinburgh and Leith, proposed a motion stating that it was essential that further power should be given to practitioners and local authorities " with a view to strengthening the voluntary system by placing a ' compulsitor ' on all persons infected with venereal disease in order to secure the submission to treatment and continuance under treatment of such persons until discharged by a registered medical practitioner." In England, he said, 63 per cent. of the known cases of venereal disease failed to complete their treatment; in Wales the percentage was 45 and in Scotland 51. In face of this could anyone say that the present schemes were successful? Few clinicians would say that we were stamping out syphilis; none would say that we were lessening gonorrhœa. The reasons were two—ignorance and carelessness. It was the duty of the profession to dispel ignorance and the duty of the State to discourage carelessness. The plan of a compulsitor as approved by every local authority and medical officer of health in Scotland did not infringe the liberty of any subject who deserved liberty. It only infringed the liberty of the libertine.

Mr. BISHOP HARMAN thought that compulsion would drive the disease underground where it would be even more destructive than at present, but Mr. E. B. TURNER, who said he had spent a large part of his life in the fight against venereal disease, having addressed 987,000 people on the subject, commended the trial of a compulsitor in selected districts, as proposed by Edinburgh, and recommended in the Trevethin Report. Dr. GRAHAM LITTLE, M.P., on the other hand, thought it useless to try compulsion locally. People would change their place of residence, and in any case defaulting was the least important of the problems of syphilis. The wholly untreated patient was the real danger to the community, not the patient whose infectivity had been reduced by beginning a course of treatment. Dr. BRACKENBURY also maintained that venereal disease could not possibly be dealt with by local option; he would rather see compulsion over the whole country than in limited areas, but Dr. LEES explained in his reply that the area covered by the Edinburgh scheme extended almost from the Forth to the Border, which made a change of dwelling, especially in this time of housing shortage, an impossibility for most patients. The percentage of defaulters at his own clinic was only 26—the lowest in Scotland and perhaps the lowest in the country as a whole. The Representative Body, by passing the resolution, would set a very necessary example to Parliament, some of whose medical Members had ideas on venereal disease some 20-30 years out of date.

The motion was lost by a considerable majority.

Miscellaneous Topics.

An unsuccessful proposal by South-West Wales that the Council should try to secure for the profession a supply of petrol (or its homologues) at commercial rates led to the statement that many garages are willing to make this arrangement with practitioners. Sir RICHARD LUCE said that medical M.P.'s had decided that it would be undesirable to ask for privileges for the profession as regards the new petrol tax.

The Representative Body decided—

> " That it is undesirable that chiropodists should be recognised in a special register as such register would convey to the public that chiropodists were competent to undertake the diagnosis and treatment of diseases of the feet."

A suggestion was put forward that the annual representative meeting should in future be held in London, to deal with medico-political questions so that the business of the annual meeting held at various centres could be restricted to scientific and social work and enlarged in scope. But the motion inviting the Council to consider this plan was lost by a large majority. The same fate met proposals to reduce the annual subscription to two guineas, and to investigate the possibility of establishing a compulsory scheme of life insurance for all members of the Association.

A further account of the deliberations of the Representative Body will be published in a coming issue of THE LANCET. In the course of the proceedings it was announced that Dr. Hawthorne had been re-elected chairman for the coming year and that Dr. Arnold Lyndon had been elected deputy chairman.

QUEEN ALEXANDRA MEMORIAL.—It is announced by the Queen Alexandra National Memorial Committee that, when the fund was closed at the end of June, the total amount received exceeded £233,000.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

CITY OF GLASGOW.

THE discrepancy between the local estimate of the population and that of the Registrar-General is now considerable, and some of the statistics for 1927, from both points of view, are here given.

City of Glasgow (population mid-year).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Diarrhœa, &c., under 2 years.	Maternal mortality from childbirth.
Local estimate.. (1,130,675)	20·9	13·7	1·14	1·33	2·5	1·6	107/36	14·4	6·6
R.-G.'s estimate. (1,049,000)	22·4	14·6	1·23	1·43	2·7	1·8	107/36	14·4	6·9

Dr. A. S. M. Macgregor's report, a volume of 381 pages, besides an account of the work of his department and the usual statistical tables, contains special sections dealing with overcrowding, the rehousing for tenants under slum-clearance schemes, the incidence of cancer, results of artificial light treatment in tuberculosis and rickets, a study of puerperal fever at Belvedere Hospital; and an inquiry into the incidence of the non-pulmonary forms of tuberculosis.

Pneumonia and Tuberculosis.

The attempt to provide hospital accommodation for pneumonia, measles, and whooping-cough was made difficult by an unusually high incidence of diphtheria, but the difficulty was relieved by the prompt coöperation of the poor-law authority in admitting patients suffering from pneumonia at times of pressure. Since the municipal hospitals opened their wards to pneumonia, there has been an increased demand and the general hospitals have apparently restricted admission of such patients.

The cases of pneumonia notified during the year numbered 6252 and the percentage admitted to municipal hospitals was 58. Pneumonia, says Dr. Macgregor, is very apt to be erroneously notified and has become a somewhat loose and ill-defined term. In the case of secondary pneumonias the primary cause is often omitted from the death certificate, and this makes it difficult to study the causes which lead to so high a prevalence of respiratory disease in young children. A considerable number of children are sent to hospital for pneumonia who are found to be suffering only from slight catarrh and thus occupy hospital beds to the exclusion of more urgent cases. As an example of the severity of acute primary pneumonia, a case mortality-rate of 26·3 per cent. is cited for 5334 children under 5 years of age, admitted to hospital during the last seven years; under 1 year the case mortality-rate reaches 40 per cent. The death-rate from all forms of pneumonia appears to have increased during the last 70 years, and recent studies suggest that overcrowding and poverty have a greater influence on this death-rate than meteorological conditions.

The death-rate from pulmonary tuberculosis has declined steadily from 1·43 in 1913 to 0·86 and 0·84 in 1926 and 1927. At the request of the Scottish Board of Health treatment with Ruppel's serum was investigated, but the serum did not fulfil expectations. There has been a great fall in the mortality from non-pulmonary tuberculosis.

Since the quinquennium 1901–05, the rate from tuberculous meningitis has fallen from 319 per 1,000,000 to 142; that from abdominal tuberculosis from 301 to 60, and that from other forms of non-pulmonary tuberculosis from 258 to 99. Tuberculous disease of bones rarely leads to amyloid disease nowadays. During May the 4567 cases of non-pulmonary tuberculosis on the register were reduced to 2811 by writing off: (1) those not suffering from tuberculosis; (2) those who had had no active disease for two years; and (3) those of whom there had been no information for two or more years. The residue included 200 under 5 years, 1311 from 5 to 15 years, and 43 over the age of 15. Of the total of 2811 43·3 per cent. suffered from tubercle of bones and joints, 25·5 per cent. from the glandular and 18·2 from the abdominal type. A further analysis showed that tubercle of bones and joints constitutes over 40 per cent. of the cases at the three age-periods mentioned, while the percentage of abdominal tubercle was 35·5 per cent. under 5 years, 23·6 from 5 to 15, and 8·1 over 15, and the glandular form constituted 14·4 per cent. of the cases under 5, 25·8 of the cases under 15, and 28·1 of the cases over 15.

The bone and joint cases are those which require prolonged institutional provision. Of 438 bone cases, 241 suffered from spinal disease. Of the 450 joint cases 205 suffered from hip disease and 127 from knee disease. The figures as regards abdominal tuberculosis are given with some reserve owing to doubt as to the diagnosis.

Owing to housing conditions, institutional treatment is often required until the patient is cured. Thus, of the groups of 2811 patients just analysed, 20 per cent. lived in 1-apartment, 62 per cent. in 2-apartment, 13 per cent. in 3-apartment, and 4 per cent. in 4-apartment houses, and upwards. In 1 per cent. there was no information.

The conclusions of Dr. T. McGowan, from the treatment of tuberculous children with ultra-violet rays at Ruchill Hospital are that the rays have a stimulating effect on all children, but that the reaction in tuberculous cases is greater, and takes the form of an auto-inoculation. Immediately after treatment there is a slight fall in weight and a marked and sustained increase in pulse-rate. The auto-inoculation is proportional to the dosage, and so long as it is not excessive produces beneficial results.

Other Infections.

Influenza was less fatal than in 1926; the mortality from scarlet fever was less; and diphtheria, in spite of increased prevalence, caused a lower death-rate.

A milk-borne outbreak of paratyphoid fever of a mild type gave rise to 67 known cases in August and September, and caused two deaths of young children already debilitated by measles. A follow-up of the 517 survivors from attacks of encephalitis lethargica shows that 245 are fit for work or school, although 104 show minor sequelæ; that 47 are unfit for school; and that 225 are unfit for work, of whom 160 are of the Parkinsonian type, 35 are mental hospital cases, and 30 show other effects. The three years' period for the notification of whooping-cough expired on July 10th, and the notification was not renewed, but visitation by nurses is being continued.

Antenatal Supervision.

During 1927 919 cases were admitted to antenatal wards of the Royal Maternity Hospital as compared with 866 in the previous year. The antenatal dispensary of this hospital was attended by 4267 expectant mothers, and the ten other antenatal centres by 2068. The total births numbered 23,578. Nearly half the expectant mothers attended before the seventh month of pregnancy.

Venereal Diseases.

Among the 47 gonococcal cases of ophthalmia neonatorum there was no damage to eyesight, and among the 358 non-gonococcal cases there was one case of impaired vision of one eye. A plan is given of the new clinic for venereal diseases, opened in October at Black-street, which has relieved the pressure on the Broomielaw dispensary. A table shows that 50 per cent. of the men under treatment for venereal disease and 10 per cent. of the women ceased to attend before completing a course of treatment, and that 3·6 per cent. of the men and 17·5 per cent. of the women failed to submit to the final tests after the completion of the course. Meetings have been held of the local authorities in the West of Scotland and, on March 22nd, 1928, the terms of a Bill for dealing with defaulters was approved at a final conference.

Housing.

The new houses completed during 1927 numbered 5183, compared with 6796 for the previous year, both figures being a considerable advance on former years. For many years it has been impossible to put in operation the statutory powers for the prevention of overcrowding in the 18,000 "ticketed" houses. The most that can be done is to prevent gross overcrowding of one house by two families. The overcrowding in the "ticketed" houses is round about 15 per cent., and when this figure falls it will be an indication that the housing shortage is being overtaken. The crux of the housing problem is the provision of houses at a rental which the working classes can afford. A provisional order is to be obtained for the better supervision of the rehoused tenants. Reports of various rehousing schemes show that about 10 per cent. of the tenants are dirty in spite of repeated warnings. It has been found, by experience, that a considerable improvement can be effected through systematic and sympathetic supervision by nurse-inspectors, and it is proposed to extend this scheme of visitation. During the last five years four slum-clearance schemes have been initiated, involving 5110 houses. Of the latter, 2068 have been demolished, 287 are closed, and 2755 are still occupied. An attempt is being made by power obtained under a local act to control and limit the excessive rentals charged for furnished houses let in tenements.

Bacteriological and Analytical Work.

From the report of the city bacteriologist, Dr. R. M. Buchanan, we learn that 42 cheap shaving-brushes were examined for anthrax with negative results, but that some of the goat-skin thongs used as binding for orange-boxes have given positive results. Of 202 milk samples examined for tubercle two were positive. Dr. Buchanan is of opinion that the tubercle bacillus cannot be satisfactorily identified by the microscopical test, but that animal inoculation is necessary for its detection. During the year 27 milks showed acid-fast bacilli, some of which were indistinguishable microscopically from the tubercle bacillus, and all of which were proved by inoculation to be non-pathogenic. Of 205 samples of designated milk, 189 reached the standard and 16 failed. In certain pasteurised milks, non-sporing cocco-bacilli, or streptococci, have been found, the growth of which appears to have been favoured by the high temperature of pasteurisation. A considerable amount of work has been done with regard to fungoid diseases of fruit, illustrations of which are given in the report. A small outbreak of irritant poisoning, apparently due to eating tinned apricots, appears to indicate that contamination with tin varies according to the quality of the tinplate and the time which has elapsed since canning. The Scottish Board of Health, however, has not felt justified in issuing regulations requiring the date of canning of foodstuffs to be recorded on the container.

The regulations with regard to preservatives in food are said to be working fairly satisfactorily, but butchers in the habit of using a chemical substance known locally as "Madame Rachel" to maintain the bloom of mince have proved somewhat recalcitrant.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 14TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 177 (last week, 182); scarlet fever, 1695; diphtheria, 919; enteric fever, 38; pneumonia, 747; puerperal fever, 33; puerperal pyrexia, 109; cerebro-spinal fever, 7; acute poliomyelitis, 12; acute polio-encephalitis, 1; encephalitis lethargica, 15; dysentery, 7; ophthalmia neonatorum, 106. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 21 counties:—London, 3; Bedford, 2; Buckingham, 1; Derby, 16; Devon, 1; Dorset, 1; Durham, 39; Lancaster, 6; Leicester, 4; Northampton, 3; Northumberland, 10; Nottingham, 6; Soke of Peterborough, 2; Stafford, 11; Surrey, 1; Warwick, 1: Yorks, East Riding, 20 (Kingston-upon-Hull); North Riding, 3; West Riding, 30; Glamorgan 9; Monmouth, 8.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on July 17th–18th was as follows:—Small-pox, 27 under treatment; scarlet fever, 1759; diphtheria, 1856; enteric fever, 17; measles, 418; whooping-cough, 172; puerperal fever, 22 (plus 18 babies); encephalitis lethargica, 66; poliomyelitis, 1; "other diseases," 27. At St. Margaret's Hospital there were 23 babies (plus 16 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 27 (3) from measles, 6 (0) from scarlet fever, 29 (7) from whooping-cough, 25 (4) from diphtheria, 40 (10) from diarrhœa and enteritis under two years, and 24 (5) from influenza. The figures in parentheses are those for London itself.

The two fatal cases of enteric fever were reported from Bath and Worcester. Of the 24 fatal cases of measles outside London 9 were reported from Liverpool and 3 from Burnley. Of the 22 fatal cases of whooping-cough outside London 4 each were reported from Birmingham and Liverpool, 3 from Manchester. In the same week Glasgow reported 10. Fewer deaths from diarrhœa are reported this week than in the two last.

The number of stillbirths registered during the week was 297 in the great towns (corresponding to a rate of 42 per 1000 births), including 52 in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

IT is officially announced that the title of the Director-General of the Medical Department of the Navy has been altered to "Medical Director-General of the Navy."

To be Surg. Lts.: F. Dolan and F. G. V. Scovell.

The following are notified: Surg. Lt. A. R. Ewart to *Columbine*. Surg. Lt. (short service) J. J. Keevil transferred to permanent list. Surg. Lts. (D) T. Hunt to *Vivid* for R.N. Barracks, Devonport; and S. E. Brown to *Defiance*.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. R. B. Ainsworth is apptd. a Professor at the R.A. Med. Coll., vice Lt.-Col. (Bt. Col.) P. H. Henderson, vacated.

To be Bt. Lt.-Col.: Maj. E. T. Potts.

To be Bt. Col.: E. A. Walker, I.M.S.

To be Bt. Maj.: Capt. T. M. Layng, 3/9th Jat. R.

Temp. Lt. M. Clayton-Mitchell relinquishes his commn. and resumes the rank of Capt.

ARMY DENTAL CORPS.

Lt. C. E. Day to be Capt.

SUPPLEMENTARY RESERVE OF OFFICERS.

A. N. T. Meneces to be Lt.

TERRITORIAL ARMY.

Maj. G. F. R. Smith to be Lt.-Col. and to commd. the 164th (W. Lan.) Fd. Amb.

Maj. W. L. R. Wood resigns his commn.

Capt. T. D. Overend resigns his commn.

Capt. C. B. Jones to be Maj.

Lts. R. K. Wilson (R.A.M.C. Res. of Off.) and H. A. C. Gregory (late R.A.M.C., Spec. Res.) to be Lts.

J. G. Weston and H. A. Bulman to be Lts.

ROYAL AIR FORCE.

The undermentioned Flying Officers are promoted to the rank of Flight Lt.: J. O. Priestley and J. Twohill.

RESERVE OF AIR FORCE OFFICERS.

Flight Lts. relinquishing their commissions on completion of service: T. A. G. Hudson and C. H. B. Thompson.

INDIAN MEDICAL SERVICE.

Capts. P. A. Dargan, C. Mac D. Nicol, and L. Blake to be Majs.

Lt.-Col. E. W. Browne retires.

Correspondence.

"Audi alteram partem."

CARDIAC CLINICS.

To the Editor of THE LANCET.

SIR,—Considerable difference of opinion has been expressed recently in your columns as to the predisposing factors in rheumatism. Dr. Reginald Miller thinks[1] that "the environmental factors at work (of which damp and cold are the most important) must to some extent centre round the production of disease-infected tonsils." Dr. W. C. Vining writes:[2] "In Leeds I found nothing to support the belief that damp plays an important part in arousing the rheumatic infection to activity." He does not believe that infected tonsils are an important factor, but regards the effect of diet as paramount. The only way of deciding between them is to obtain and compare figures collected from all the main centres of population in the British Isles.

Last year I was fortunate enough to be closely associated with the formation of a children's cardiac clinic at the Johns Hopkins Hospital, Baltimore. Preparatory to this I had inspected all the main clinics of this nature in New York, Boston, New Haven, and Philadelphia. A fallacy has grown up in England that rheumatism is almost unknown in America, probably due to the fact that American physicians coming from the Southern and Western States, where the disease is rare, are always demanding to be shown rheumatic nodules in London hospitals. This does not apply to the Northern States, and New York claims nearly as much rheumatism as London. So much is this the case that a definite effort has been made to study the disease by means of an elaborate organisation centred in New York with cardiac clinics allied to it all over the country. In these the notes are taken on special forms, carbon copies of which are sent to the headquarters in New York.

The most perfect of such clinics for children is probably that of Dr. May Wilson, at the Nursery and Childs Hospital, New York, where a clinic of 500 children has been in existence for nearly ten years. Case notes are taken on the special forms mentioned, and the children classified into five groups:—

I. Able to carry on habitual physical activity.
IIa. Able to carry on with slightly diminished physical activity.
IIb. Able to carry on with greatly diminished physical activity.
III. Symptoms of heart failure at rest.
IV. Abnormal signs and symptoms.
V. Potential heart disease (uncomplicated chorea, &c.).

This classification is based on a careful history and physical examination, combined with a fluoroscopic tracing of the heart, the vital capacity, exercise tests, and in some cases electrocardiograms and leucocyte counts. Controversy has raged over the value of these tests, and from my own work which, in my opinion, is but relative, the tests being of little use if performed on a single occasion. In the case, for instance, of two children of the same age and size, who are eventually classified in the same group, one may have a different normal vital capacity than the other. The tests are, however, of great assistance in judging how any one case is progressing. If a child is going down hill, or if reinfection has taken place in an old case, although the weight, temperature, pulse, and physical signs may show little change, the vital capacity will usually fall at once, the heart will show a longer interval before it returns to normal after exercise, the leucocyte count will rise, while the fluoroscopic tracing will often show a slight dilatation that percussion has failed to demonstrate.

These clinics are of inestimable value to the child who is under the constant care of the same physician over a number of years, and eventually handed on to an adult clinic with a complete clinical history. At the same time the clinics amass statistics which are easily examined. Dr. Wilson, for instance, has shown that tonsillectomy has little or no beneficial effect on chorea, and only slightly more on other forms of rheumatism; that rheumatism is not confined to the very poor, but is common in the children of the artisan class. Surely, if a system of clinics, modified to suit the conditions, were established in all the great medical centres of this country, where rheumatism is so universal, and its clinical interpretation so generally understood, it should be possible to amass such a vast number of figures, that the problem of predisposing factors could rapidly be settled. If at the same time these clinics were in close touch with laboratory research, it is not too much to hope that the great problem of what is the infecting agent, which has baffled the profession for so long, might at last be cleared up, and a new era inaugurated for the treatment of the disease.

I am, Sir, yours faithfully,

W. ROBERT F. COLLIS, M.B. Camb., M.R.C.P.,
late Temp. Assistant Physician, Johns Hopkins Hospital.
July 14th, 1928.

RESULTS OF SURGERY IN CARCINOMA OF THE CERVIX UTERI.

To the Editor of THE LANCET.

SIR,—I should be much obliged if you would allow me to correct the figures appearing in the report of the remarks I made last week at the International Conference on Cancer in your last week's issue (p. 142). These figures should read:—

> Up to the end of 1927 he had performed Wertheim's operation 351 times. There were 53 deaths due to the operation—an operative mortality of 15·1 per cent. Of the 298 patients who survived the operation, 139 had died of recurrence, and of the remaining 159, 13 had died of other disease, of whom 6 survived over 5 years (3 survived over 10 years) and 30 had been lost sight of, 17 after they had passed the 5-year limit (5 had passed the 10-year limit), and there were 116 patients whom he was still in touch with. Of these latter 64 had passed the 5-year limit (35 had passed the 10-year limit), whilst the remaining 52 had been operated on at periods less than 5 years ago. In all, then, 87 patients had survived the operation 5 or more years, 43 of whom had survived it 10 or more years.

I am, Sir, yours faithfully,

VICTOR BONNEY.

Devonshire-place, W., July 24th, 1928.

DIPHTHERIA CARRIERS.

To the Editor of THE LANCET.

SIR,—I was much interested in Mr. Yearsley's letter on the occurrence of Klebs-Löffler bacilli in the cavity of a decayed tooth. I came across one such instance myself during my investigation on diphtheria carriers. The case was, briefly, as follows:—

> A boy of 5 years of age had shown persistently positive throat and nose cultures for several months. He had very decayed teeth, and it was thought that these might be acting as foci for the growth of K.L.B. Cultures were taken from the gums around the base of six of the most decayed teeth. Yeasts were obtained from all of the teeth sockets, and, in addition, K.L.B. were obtained from the region surrounding a decayed right upper incisor. These decayed teeth were all removed, but the throat and nose cultures still remained positive, and the child did not clear up until he was put on nasal douches.

I did not allude to this case in my article, as I regarded the occurrence as too rare to be of practical importance.—I am, Sir, yours faithfully,

WM. CLUNIE HARVEY.

Borough Sanatorium, Brighton, July 22nd, 1928.

THE MAINTENANCE OF ORPHANS OF MEDICAL MEN DURING THE HOLIDAYS.

To the Editor of THE LANCET.

SIR,—The applications for assistance from the Royal Medical Benevolent Fund have in recent months been exceptionally numerous and urgent. A special plea which appears at this time of the year is for help for children. In coöperation with our Ladies' Guild and other bodies the Committee of this Fund is often able to secure admission of children of deceased medical practitioners to orphanages or schools where free education is given.

During the holidays provision must be made for these children, and when there are no friends or no friends in a position to receive them, the difficulty is great. The Committee does what is possible, but their efforts are much hampered by the lack of funds. Further subscriptions and donations will be gratefully received at 11, Chandos-street, Cavendish-square, London, W.1.

I am, Sir, yours faithfully,

July 23rd, 1928. THOS. BARLOW, President.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

CRITICISM OF HOME OFFICE ADMINISTRATION.

ON July 11th the House went into Committee on a vote of £283,588 for the salaries and expenses of the Home Office, Mr. J. F. HOPE (Chairman of Committees) being in the chair.

Factory Inspection.

Mr. RHYS DAVIES moved to reduce the vote by £100. He said that he did not think there was a better test of the efficiency of the Home Office than the number of accidents to workpeople in the factories and workshops of the country. In 1926 there were 139,963 accidents of that kind of which 806 proved fatal. In 1927 the number had reached the colossal figure of 156,974, of which 973 proved fatal. That was to say, that there was an increase in one year of 17,011 in the total number of accidents and of 166 in the number of fatalities. The Home Office had issued a circular dated May 16th, 1927, to employers stating that the Home Secretary had been much concerned to learn from the Chief Inspector of Factories that progress in the development of "safety first" arrangements in factories continued to be disappointingly small. The need of such an arrangement in industry elsewhere was great. The total number of accidents reported in the Factory Department showed no sign whatever of any substantial reduction. That circular showed that the Home Office was fully aware of what was happening in regard to the alarming growth of accidents in factories and workshops. He would not say a word against the personnel of the inspection department of the Home Office, but he felt sure that there was a distinct relationship between the number of accidents on the one hand and the number of inspectors employed and the number of visits paid to factories and workshops on the other. In 1914 there were 222 inspectors; that number has dwindled since until at the end of March, 1928, the number stood at only 206, or a decrease of 16. While the best employers no doubt did their duty according to the rules and regulations issued by the Home Office, there were some employers who paid no heed to the law in this respect and did all they could to escape their responsibilities. He urged that there ought to be an increase in the number of factory inspectors, and more women inspectors ought to be employed. He was delighted that the Home Office had instructed Sir Malcolm Delevingne to deliver a speech at Geneva in favour of a "Safety First" Convention, but it was very little use asking for an international convention in favour of the prevention of accidents when this country was not doing all it could in that direction on behalf of its own workpeople. There was another point which he would like to raise. In 1926 Parliament passed an Act prohibiting the use of white lead in painting for interior purposes. The time had arrived when they ought to know the results of the operation of that Act. He was a little alarmed at the figures relating to lead poisoning generally. In 1922 the number of cases reported to the Home Office was 247 with 26 deaths. The number grew until in 1924 it reached a peak figure which was very alarming indeed. The number of deaths in 1927 was reduced to 14, but the reported cases numbered 249 for 1927, or an increase of 2 over 1922. With regard to lead poisoning among house painters the figure in 1922 was 40 cases with 12 deaths, but in 1927 there were 98 cases reported and 21 deaths. That was indeed an alarming state of affairs. He would like to know how many offences had been notified under the 1926 Act and how many convictions had been obtained. In 1924 a Committee was appointed to inquire into artificial humidity in textile and non-textile factories, and he would like to know what had become of the recommendations of that Committee. A great many of these difficulties would have been cleared away if the Government had carried out its promise to pass a Factory Bill. It seemed to him that the Home Office ought to deal at once with the question of humidity in textile factories because the mortality and sickness figures of some of the approved societies covering textile operatives were really alarming, and some of the diseases shown in the statistics were attributable in part, he understood, to excessive humidity in these factories. He was pleased that the number of new cases of miner's nystagmus was apparently declining. In 1908 the new cases were 386, in 1914 3218, and in 1926 1771. He would like to know what means were being taken to prevent this disease spreading and to deal with it better under the Workmen's Compensation Act. He understood that the Home Office was already conducting an inquiry into silicosis, and he could assure the Government that it was high time that something was done. The problem was urgent because of the increased suffering among coal-miners from this disease. In 1922 there were 45 cases of anthrax reported to the Home Office and five deaths, and he was pleased to say the figures had declined in 1927 to 31 and 2 respectively. The Home Office had appointed a Committee to inquire into the cost of disinfecting East India wool, which was very largely responsible for a number of anthrax cases in this country. He was told that cases had occurred in Bermondsey where men had contracted the disease from hides and skins. He wished to ask whether all these materials could not be disinfected before leaving the port of origin. What was the international position in this matter? He would say, in conclusion, that it was not good enough that in these enlightened days, when they had a much better medical service and better safeguards in factories and workshops, that they should have to register 17,000 odd accidents in 1927 over 1926.

Certifying Surgeons.

Mr. HOLLINS complained of the cumbersome method which surrounded the operation of the Workmen's Compensation (Silicosis) Act of 1918. The Act could only be applied to those industries which made application and for which the Home Office made an Order. Committees had to be appointed and investigations made, and the greatest difficulty was the obstructive methods which could be adopted either by the employers' representatives or the workers' representatives. In the three industries which up to the present had been before the Home Office inquiry there was only one happy result. Owing to this cumbersome machinery and the waste of time involved in obtaining an Order, a very meagre fraction of the total number of workers affected had been brought under the scheme since the Act was passed. The only proper method was to have the disease scheduled as an ordinary occupational disease. Lead poisoning was a cumulative disease and one never knew when the effect would show itself. Persons had shown symptoms of the disease several years after they had left the lead process, and because of the lapse of time since they had worked the process they could not make a claim for compensation. He would urge that if the Home Office could not extend the limit of time indefinitely during which a lead process worker could make such a claim it ought, at any rate, to be extended to a period of three or five years. The present method of appointing certifying surgeons was not a proper method. The best men might be appointed, but they were not appointed because they were experts in lead poisoning, silicosis, or anthrax. In the pottery industry they were paid 1s. per examination, with the result that cases had been known where 20 workers had passed before the certifying surgeon in as many minutes. It was impossible for anybody to make an examination of workers in so short a period of time. Certifying surgeons should be whole-time men without private practice. This had been tried in the Refractories Industries scheme when the tuberculosis officers made the examinations in the first instance. Afterwards permanent full-time men were appointed and it was found that the examinations were more efficient and the data more valuable. He hoped that the Home Secretary would give his attention to the three points he had raised.

Mr. MACKINDER said as one connected with the textile trade he wished to emphasise what had been said regarding the insufficient staff of factory inspectors. He had been from 1914 until last year a member of the Departmental Committee on Anthrax. In 1927 19 cases from wool were reported, three from horsehair, nine from hides and skins, and one from other industries. He would like to know how many of these cases were fatal and how many non-fatal. He did not know whether it was possible—he hardly thought it was—to disinfect the hides in the country of origin, but he was quite certain that it was possible to disinfect the wool in the country of origin. He knew that the number of cases of anthrax was largely decreased as the result of the operation of the very fine Government disinfecting station at Liverpool, but that only dealt with Persian and Egyptian wool, and there were any number of dangerous wools. There was goat hair and camel hair which were also dangerous. He would like the Home Office to interest itself in the inspection of the material used in the production of shaving-brushes. He did not know whether the Home Office was aware of the tremendous danger that the public were running from the use of shaving-brushes made from what was called Chinese tail, or mane hair, which was a material liable to be infected with anthrax. It reached this country in a roundabout way and was made into the cheapest imitation badger hair shaving-brushes, from which it was very easy to get this dangerous and loathsome disease. The Departmental Committee proved that it was possible to get these brushes and materials disinfected and made safe.

A Second Ministry of Health.

Lieut.-Colonel FREMANTLE said that the latest figures with regard to lead poisoning given in the report for 1926 were certainly disconcerting. It was true that there were fewer cases, but there were something like double the number of deaths from lead poisoning in the last year reported upon as compared with the previous year, and that was a matter which needed to be cleared up. It was no doubt too early to get definite information as to how far the Act of 1926 had taken effect; but if the Home Office could give them any information they would be glad to have it. The general line of the 1926 Act was to prohibit painting by women and young persons and to give power to the Home Secretary to issue regulations. That he thought was the right method. He objected to prohibition wherever it was possible to avoid it. They wanted to work up as much as possible the question of education and inspection. The factory inspector was one of the most valuable administrators and forms of education. But they could not expect to get efficient inspection when the inspectors came from a distance. They must delegate the people who were on the spot, who could drop in and see how things were going on. There was already a certain amount of sanitary inspection and the sanitary inspectors and medical officers of health had to furnish copies of their annual reports. He wanted to extend that system. He believed that they could extend it very considerably in the larger cities and boroughs, where they could use the local medical officer of health more and more. That was a matter which had to be remembered when they were considering the inadequacy of the inspectorate and the actual official reply that they could not afford to have more inspectors. He thought they were on the wrong line if they were seeking to increase the centralised bureaucratic inspectorate. They ought to open up the factory system to local people, who would gladly take an interest in it. He was afraid that the suggestion made by Mr. Hollins that certifying surgeons should be whole-time men was quite impracticable. These surgeons had to be dotted about all over the place. They ought to be given an opportunity of being more useful than they were at present. The certifying factory surgeon only had certain inspections detailed to him when called for by the factory inspector. He could not be expected, therefore, to sift through the whole of the cases that could be improved because he only had cases of definite illness or cases that required attention by the lay inspector. He would like to have some account of the extremely beneficent welfare work in the factories which had been extended so much since the war. It was a very hopeful work, instituted during the war in the Department of Munitions by one of the factory medical inspectors attached to the Ministry for the purpose, and the Home Office had followed it up since. His latest information was that statutory welfare orders had been made for 14 industries so far. He would be glad to know if they were going to be extended further. He had always taken intense interest in the Factory Department of the Home Office. It was nothing less than a second Ministry of Health on which the health and efficiency of the nation depended.

Mr. JENKINS said that in consequence of recent appeals in regard to the effect of silicosis among miners the Home Office had appointed a medical man, but one medical man for the whole country was totally inadequate to meet the needs of the mining and other industries and to investigate and make reports on cases. The Home Office ought to appoint larger staffs of medical men for this purpose. The same applied to nystagmus.

Reporting of Accidents.

Dr. VERNON DAVIES said that he was an old certifying factory surgeon of over 20 years' experience. There had been a justifiable complaint that evening of the small number of factory inspectors. During the war the Home Office took what he regarded as a very retrograde step. Up to that period practically all accidents were notified to the certifying factory surgeon, who had to visit the factory to see the identical place where the accident occurred, to get a report, then proceed to see the injured person and get his or her report, and finally to issue a report to the factory inspector and so to the Home Office. By that process two or three very important things were done. In the first place they were sure that the mill authorities reported the majority of their accidents, because they never knew what doctor a particular patient might go to, and news of an accident might leak out and reach the factory surgeon. Therefore they were compelled to carry out the regulations and report their accidents more closely. The second good point was that it enabled them to forward true accident reports. On more than one occasion he found in his investigations that the report sent to him by the mill authorities was not accurate. On the other hand he knew from his experience that unfenced machinery was not always the fault of the employers. It was sometimes the fault of the workers; they did not like the guard, and they removed it. The Home Office decided to do away with this reporting of accidents to the certifying surgeon because it cost the country the enormous sum of £7000 per annum. It was quite possible to report an accident so as to create a false impression, and it was possible that there were many accidents which ought to be inspected by the factory inspector which were not so inspected. Therefore in his opinion the Home Office took a retrograde step by cancelling the reporting of accidents by certifying surgeons. That procedure was to the advantage of the Home Office, to the advantage of the workers, and to the advantage of the mill, and he hoped that some time or other they would reconsider the position and see if they could not go back to the old method of reporting accidents. The fact that the mill authorities knew that the factory doctor might be in the mill any day kept them up to the mark. With regard to nystagmus the figures were going up. Some time ago, when he was looking at the figures for Belgium, he found that there was not the same rate of increase in nystagmus there as there was in this country. In Belgium compensation was only given for nystagmus for a certain definite time, at the end of which the compensation ceased, and for some remarkable reason the cases improved. That reminded him of the old days of the "railway spine," when people after railway accidents got concussion of the spine and never got better until the case was settled by the company. Sir William Thorburn, an eminent surgeon who was probably the greatest expert on "railway spine" in Europe, came to the conclusion and advised all his clients that the patient would never get better until the claim was settled. These people were not malingering, but there was some psychological condition which prevented them getting better until their claim was paid. He wondered whether in this country the same sort of thing was happening in regard to nystagmus, and whether it would not be better instead of saying that the man should be paid so much per week to give him a lump sum by way of compensation, which might have some effect on the recovery of the patient.

Mr. CONNOLLY: Do you think that as a medical man?

Dr. VERNON DAVIES said that he was arguing this matter from a medical standpoint and suggesting that a new method of compensation might be tried as an experiment. Silicosis was becoming more important every day, and he thought that it had been grossly neglected in this country. It really was rather astonishing, considering our huge mining industry, employing an enormous number of men, that a medical man should only have been appointed a few months ago by the Government for the first time to advise them on the medical conditions affecting this industry. The mining industry had been run for years [illegible] supervision. Another remarka[illegible] wished to work in a factory or workshop it had to be examined by a certifying surgeon who certified whether the child was fit to work or not. That was not the case so far as the mines were concerned, and over and over again he had refused to pass children for work in the cotton mills because they were not strong enough, but they could laugh at him and go and get work in the pits without any examination at all.

Sir VIVIAN HENDERSON, Under-Secretary for the Home Office, said that that matter was not under the control of the Home Office.

Miners and Silicosis.

Dr. VERNON DAVIES said in that case he would not pursue the subject. Silicosis by itself was not a very dangerous disease. The worst it did was to cause shortness of breath and perhaps a little difficulty in breathing. The danger came in when it became contaminated or infected with tubercle, and when they got that condition it was extremely dangerous and fatal. Considering the risks which miners ran in working in this rock dust it was high time that stringent regulations were made by the Home Office to deal with the problem. They had to bear in mind that certain people were perhaps more liable to infection by tubercle than others, and therefore in any scheme brought up to deal with the matter the health of the miner prior to and during his employment was very important. In any scheme brought forward to make silicosis a scheduled disease he presumed that the Home Office would have some control. He was convinced that the examination of the patient for silicosis should not be given to ordinary medical men, but should be done by Home Office specialists, because it was extremely difficult to diagnose accurately, especially in the early stage. It was very essential to have an expert radiographer, and the Home Office should consider the advisability of appointing a few specialists in this particular disease who could go round the country examining patients at different mines at definite regular periods. It was no use waiting until the man could not work; he should be examined regularly. It would only be necessary to examine the mines where there was a large amount of silica. Coal dust itself did not produce silicosis; in fact it did good, because it lessened the liability to consumption. Colliers were among the healthiest people in the country, and statistics proved that they were less subject to pulmonary tuberculosis than any other grade of workers, except agricultural workers. If his suggestion was carried into effect they would improve the health of the miner and prevent a certain number of deaths by getting a man away from the pits when he was in a recoverable state.

Shuttle-kissing.

Mr. T. **Shaw** said there was a museum in London which contained an extraordinarily interesting collection of safety appliances for machines and also a number of diagrams of great interest and value to those engaged in industrial occupations. He wished to pay his tribute to that part of the Home Office work and to express the hope that it would be developed. The principal thing to which he wished to refer—and he believed that the matter could be dealt with by administrative order from the Home Office—was the practice known in Lancashire as shuttle-kissing. They never could get a body of medical opinion to say that this practice was dangerous, yet nearly every weaver over 20 years of age in Lancashire had either very badly decayed teeth or was wearing artificial teeth. Surely there was a connexion between the constant kissing of the shuttle with the drawing of the weft and the dust into the mouth and this extremely high average of decayed teeth among weavers. In any case it was a disgusting, dirty, and dangerous habit. It often happened that during an influenza epidemic a weaver left his work with influenza. The weaver who took his place used the shuttle and quickly went off work with influenza. It often happened that two, three, or even four weavers used the same loom and the same shuttle and went off work one after another. Further, in cases where colours were used of a free type the weaver had his lips and mouth dyed by the colour that was used. He had seen weavers with their lips, teeth, and inside of the mouth green, blue, and red, and the whole of their arm covered with a kind of fine dust which "ran" when perspiration took place. They could understand what it meant to a person drawing that kind of thing into the mouth day in and day out. He distinctly remembered a case which happened in his youth when he was working in a mill. A man who was afflicted with a very loathsome disease went away from his work and the man who followed him on his looms contracted the same disease. Nothing ought to stand in the way of the replacement of the shuttles by hand-threaded shuttles, if that could be done. He asked the Home Office seriously to consider making an order which would do away with this dangerous and disgusting practice.

Lieut.-Colonel **Watts-Morgan** urged the appointment of a larger number of medical men to carry out research work and inspection. He also suggested that compulsory insurance against injuries sustained by these workers should be applied to all colliery companies.

Mr. **Connolly** referred to certain new draft regulations which he said were about to be issued by the Home Office in connexion with the use of the oxy-acetylene welding machine in ships and elsewhere. This question arose out of a fatal accident on the Mersey in which two men lost their lives through an explosion in a confined space. The proposed new regulations which he believed were based upon that accident provided that prior to a welding operation by the oxy-acetylene machine there must be first of all a purifying of the air in the space where the machine was to work and that during the operation there must be a continual supply of fresh air. That was all very well as far as it went, but to meet practical needs the use of this machine in confined spaces ought to be totally prohibited. Provision should be made that nothing but the electric welder should be used in cases of this kind.

Under-Secretary's Reply.

Sir V. **Henderson**, replying to the debate, said that if they were going to make any comparison of figures relative to industrial accidents the two years that they ought to compare were 1927 and 1925. In 1925 there were 159,693 accidents, of which 944 were fatal, as compared with 156,974 in 1927, of which 973 were fatal. Therefore on figures alone he did not think that any great case could be made out against the Factory Department of the Home Office. He agreed that there was a slight reduction in the inspectorate compared with the pre-war staff. The present position, he admitted, was not satisfactory, and he hoped it might be possible to obtain an increased number of inspectors. But there had been no slackening in regard to the inspection of factories. That inspection had been more complete and thorough than in previous years, and if there had been any slackening it had been in regard to the inspection of small workshops where there was not generally the same risk. This question must to a large extent be mixed up with that of the Factories Bill. That Bill had been held up for the moment—he hoped only for the moment—but when it reached the Statute Book it would carry with it obligations on the Factory Department which would necessitate an increase in the number of inspectors. In order to show that the Home Office really had this matter at heart the Home Secretary had promised in the autumn to set up a small committee to go into the question of the staffing and organisation of the factory inspectorate at the Home Office, and he (Sir V. Henderson) hoped that he might be chairman of that Committee. Therefore the matter would not be lost sight of. As a result of the "Safety First" circular, which had been referred to in the debate, the Home Office had received very satisfactory assurances from a number of important employers' organisations, and they were assured that the matter was bearing fruit by reports they had received from their inspectors. As regarded the danger from shaving-brushes infected with anthrax, the Ministry of Health already had power to prohibit the importation of dangerous brushes. A proposal had been made to both sides of the painting industry to coöperate with the Home Office in carrying out the lead paint regulations. That coöperation had been given and the figures proved that the position was improving. So far as nystagmus was concerned, he had not the figures for 1927. The Home Office was only concerned with nystagmus from the point of view of compensation and not from that of prevention, which was a matter for the Mines Department. He fully endorsed everything which Mr. Mackinder had said about the excellent work which was being done at the disinfecting station at Liverpool, but he would realise that it was not possible for that station to deal with the disinfection of hides. No satisfactory system had yet been discovered for that purpose, although inquiry was being made. The report as to the further scheduling of wool for disinfection was now in the hands of the Home Secretary, but had not yet been published. From the point of view of expense it was extremely reassuring—much more so than some people anticipated. Hon. Members ought to rest assured that this matter would receive very sympathetic consideration. So far as the international aspect of the question was concerned, Australia and India had always refused to coöperate, and so long as that attitude was maintained it was really impossible to deal with the question internationally. The question of silicosis was surrounded with enormous difficulties. Whilst the Home Secretary was prepared to consider whether he could amend or improve or expedite matters it was quite likely that it would entail legislation, and therefore he (Sir V. Henderson) could not discuss it that night. With regard to what Mr. T. Shaw had said about shuttle-kissing, the Home Secretary had announced that he would be quite prepared to consider dealing with it in a clause in the Factories Bill if he could have some general information that it was desired by the vast majority of the workers concerned.

Mr. **Shaw** said that he would give that information at the earliest possible opportunity.

Sir V. **Henderson** said that he was inclined to agree with some of the strictures passed by Mr. Hollins on the subject of certifying surgeons. But if they were going to alter the whole system of certifying surgeons legislation would be required, and therefore it was a matter which he could not discuss in detail that night. There was also a very important matter which not only arose generally as to the certifying surgeons, but particularly in regard to silicosis, and that was that they knew that the certifying surgeon in normal circumstances was not competent to examine silicosis cases. If they were to alter the whole position of the certifying surgeon and have a full-time medical expert on a definite salary they would have to get a Home Office medical staff or something of that kind. Quite apart from legislation that would require some compensation fund or medical fund into which the employers would pay, so that the medical men could be paid for their services. The matter was extremely complicated, but it was being looked into. While he would be glad to look into the point raised by Mr. Connolly in regard to the use of the oxy-acetylene welding machine he was not prepared to give any definite undertaking on the matter at the moment.

The motion to reduce the vote was negatived by 212 votes to 110.

BILLS ADVANCED.

The Food and Drugs (Adulteration) Bill passed through Committee on recommitment in the House of Lords on Wednesday, July 18th. This measure passed the Report stage in the House of Lords on Thursday, July 19th. The Child Destruction Bill was read a first time in the House of Commons on Tuesday, July 17th.

In the House of Lords on Monday, July 23rd, the Marriages (Prohibited Degrees of Relationship) Bill was read a second time. The Food and Drugs (Adulteration) Bill was read the third time, and passed. The Reorganisation of Offices (Scotland)Bill passed through Committee.

HOUSE OF COMMONS.

WEDNESDAY, JULY 18TH.

Lysol Poisoning.

Sir F. MEYER asked the Home Secretary whether his attention has been called to the numerous deaths, either accidental or suicidal, following upon the taking of lysol, which had recently been reported, and if he could state the total number of such deaths during 1927 and also during the first six months of 1928.—Sir W. JOYNSON-HICKS replied: I am aware that of recent years there has been a considerable increase in the number of deaths from the taking of lysol, and my Department has brought the relevant mortality statistics to the notice of the Inter-Departmental Committee which is considering the law relating to the sale of poisons. The figures for 1928 are not yet available: those for 1927, which are provisional, are as follows: Deaths from lysol poisoning: by accident, 13; by suicide, 361.

Registration of Births and Deaths.

Sir NICHOLAS GRATTAN-DOYLE asked the Minister of Health whether the registration of births and deaths, under his plans for the reform of the machinery of local government, would be severed from the poor-law administration. —Mr. CHAMBERLAIN replied: The exact arrangements to be made in regard to the registration service in connexion with the scheme of local government reform are still under consideration, and my right hon. friend regrets that he is not in a position to make a statement on the subject.

THURSDAY, JULY 19TH.

The Dangers of the Use of Allonal.

Mr. Robert Young asked the Secretary of State for the Home Department whether the German drug allonal was among those governed by the Dangerous Drugs Act: if not, whether he was aware of the growing demand for this drug and of the danger entailed in its use; and whether he would take steps to ensure that allonal should not be available without a doctor's prescription.—Sir WILLIAM JOYNSON-HICKS replied: The Dangerous Drugs Acts do not apply to "allonal," which is understood to be the proprietary name given by a Swiss firm of manufacturing chemists to a derivative of barbituric acid. I am aware of the dangers, and have brought the question of the need for further restrictions in the case of these drugs before the Inter-Departmental Committee which has been examining the law relating to poisons.

Slaughter of Tuberculous Cows.

Mr. BUXTON asked the Minister of Agriculture the number of cows affected by tuberculosis which had been slaughtered in 1926 and 1927 in pursuance of the Tuberculosis Order. 1925: and whether he was satisfied that the order was fully operative.—Mr. GUINNESS replied: The number of cows (including heifers) slaughtered under the provisions of the Tuberculosis Order, 1925, in 1926 and 1927 is 16,522 and 16,708 respectively. Local authorities have now completed their arrangements for carrying out the requirements of the Order, and I am satisfied that the Order is properly executed.

Mr. BUXTON: Does the Minister not think that in view of the increase, an increase in the staff of inspectors is needed? —Mr. GUINNESS: I do not think so; the local authorities seem to be carrying out their duties satisfactorily.

Treatment of Lunacy and Mental Disorders.

Mr. PETHICK-LAWRENCE asked the Minister of Health what steps, if any, he was proposing to take to implement the administrative recommendations of the Royal Commission on Lunacy and Mental Disorder; and, in particular, whether he could see his way to do anything for those suffering from the effects of sleepy-sickness who were not suitable either for lunatic asylums or poor-law institutions.—Mr. CHAMBERLAIN replied: I have arranged that the administrative recommendations of this Commission are borne constantly in mind in the day-to-day administration of the Lunacy Acts, and are worked to so far as is practicable in present circumstances. The problem presented by the after-effects of encephalitis lethargica is under constant review: and it will no doubt be possible to deal with certain of these patients under the Mental Deficiency Act passed last year, which amended the definition of mental defect for this purpose.

Dr. Voronoff's Experiments.

Mr. BRIANT asked the Secretary of State for the Home Department if the licences granted for permission to practise vivisection include power to carry out such operations of the grafting of glands as had been practised by Dr. Voronoff in other countries.—Sir WILLIAM JOYNSON-HICKS replied: I assume that the hon. Member refers to the reported experiment on a monkey to which his question of June 13th related. No such experiment has been, or will be, permitted in this country.

Deaths from Puerperal Causes.

Mr. VIANT asked the Secretary of State for the Home Department whether he was prepared to order that an inquiry shall be held in all cases where death had resulted from puerperal causes.—Sir WILLIAM JOYNSON-HICKS replied: I have no power to make such an order. But I understand that my right hon. friend, the Minister of Health, is arranging, with the concurrence of the British Medical Association, for maternal deaths to be investigated for scientific and public health purposes by competent medical officers in each area, and that these investigations will be considered by the Committee on Maternal Mortality which he has recently appointed.

Voluntary Health Insurance Contributors.

Major CARVER asked the Minister of Health if he was still considering the possibility of grafting on to existing national health insurance a scheme for the benefit of voluntary contributors other than those now included.—Mr. CHAMBERLAIN replied: The possibility of widening the scope of voluntary insurance under the joint scheme of National Health Insurance and contributory pensions is still under consideration, but I regret that I have not yet found any satisfactory solution of the very serious difficulties which any such proposal presents.

MONDAY, JULY 23RD.

Exemption from Duty of Scientific Films.

The House considered the Finance Bill on Report.

Captain FRASER moved a new clause, providing that the Customs duties imposed by Subsection (1) of Section 3 of the Finance Act, 1925, on negative and positive cinematograph films should cease to be payable in the case of a film which was certified by the Royal Society of London for Promoting Natural Knowledge to be solely an illustration of scientific investigation for exhibition before members of a recognised scientific body, and which was imported only for the purpose of such exhibition free of charge. The clause also provided that if any person exhibited otherwise than as provided under the clause, any film which had been exempted from duty under the section, he should, on summary conviction, be liable in respect of each offence to a fine not exceeding £50. Captain Fraser said that in 1925, under the Finance Act, a tax was placed on films imported into this country. At that time it was probably not realised that films, apart from being a means of amusement and education, were also sometimes used as a record of scientific work of no interest to the general public, but of very great value to a limited number of scientific workers. In the last two or three years great developments had taken place in the technique of the use of films as a record and illustration of scientific research. It was generally agreed that it was undesirable to place a tax upon scientific work, or indeed upon knowledge of any kind. When the matter was discussed on an earlier stage of the Finance Bill, the Financial Secretary to the Treasury and the Chancellor of the Exchequer said that the administrative difficulties were very great, but that they would do their best to meet the point. He (Captain Fraser) was happy to say that, by the instructions of the Chancellor of the Exchequer, conversations had taken place with the Customs officials which led him (Captain Fraser) to suppose that this clause could be worked by them if the House wished to pass it. He was able to say that the Royal Society would undertake the liability which it was suggested they should be asked to undertake. He therefore asked the Financial Secretary if he would accept the clause. He could assure him and the House that if he was willing to do so, men of science would be very grateful and that it would be a gesture of goodwill to those who were doing most valuable work. (Cheers.)

Mr. CRAWFORD, in seconding the clause, said that if the Government could make this concession it would be a help to the scientific and medical world. It would also give a stimulus to a small, but very notable, industry in this country which was concerned in the development and preparation of the best kind of film. He had within his own knowledge two establishments in London where, with the slightest encouragement, negatives of films of all sorts would be sent from all over the world—films which it was desired should be treated in the most expert way possible. This industry had been interrupted a good deal by the imposition of duties on the films, and he hoped the Financial Secretary to the Treasury would realise that if he could make this concession he would do a great deal to help this industry, and would help the scientific world and give a tremendous stimulus to the preparation of scientific films for use in medical and surgical cases.

Mr. A. M. SAMUEL (Financial Secretary to the Treasury) said that he remembered the previous discussion on this matter. The Chancellor of the Exchequer and he were on that occasion very sorry that they could not then accept the new clause for the reason that it was difficult to get a definition of "scientific investigation." The Chancellor of the Exchequer then said that he would look into the matter and see if he could find a way out. He (Mr. Samuel) was very glad to say that he could now accept the clause. They had found a way out to help Captain Fraser. The Royal Society of London was good enough to say that it would certify, when required, a film that was said to be an illustration of scientific investigation. That was a statement which the Customs officials could easily accept. He could not pledge himself as to the cost, but he did not think it would amount to more than £200, and probably would not be so much as that, because in many cases films would not be imported if the duty were imposed on them. The Government were delighted to be able to accept the clause. (Cheers.)

The clause was read a second time and added to the Bill.

Women Officials in the Board of Education.

Mr. PETHICK-LAWRENCE asked the President of the Board of Education whether his attention had been drawn to the fact that, excluding the inspectorate, and those employed on clerical duties, there were no women in the Board of Education; and whether, in view of the desirability of associating women with this work, he would take steps when future vacancies occurred to appoint women by promotion, transfer, or otherwise to responsible posts under the Board.—Lord EUSTACE PERCY replied: In addition to the women inspectors and women executive and clerical officers, the Board of Education staff includes a chief woman medical adviser, two women medical officers, a woman administrative officer, and a woman librarian. A woman was among the six candidates recently interviewed for a vacancy in the administrative class, which was filled by promotion, and women are equally eligible with men for vacancies filled from the Civil Service competitive examination.

Social Hygiene in the Colonies.

Viscount SANDON asked the Secretary of State for the Colonies whether the Under Secretary of State, on his recent visit to the Straits Settlements, investigated any of the problems dealt with in the 1924 Report on Social Hygiene; whether the situation was now better or worse than at that time: and whether any further steps were to be suggested or taken to remedy the evils that were therein stated to exist.—Mr. AMERY replied: The Under Secretary of State for the Colonies had some discussion about this matter with the Governor of the Straits Settlements and his advisers during his recent visit to Malaya. The Government concerned are proceeding on the lines recommended by the Committee in question, which recognised that improvement in this, as in other matters of social welfare, must necessarily be gradual. I understand that the situation already shows some improvement, and that it is not considered that any steps other than those recommended by the Committee can usefully be taken at present.

TUESDAY, JULY 24TH.

River Pollution and Public Health.

Sir ARTHUR CHURCHMAN asked the Minister of Health whether his attention had been called to the serious pollution of the River Gipping caused by effluent from the artificial silk works at Stowmarket; whether he was aware that there had been numerous cases of illness among human beings and poisoning of stock as a result; and whether, to avoid the consequences of further delay in abating the nuisance, he would authorise the local authorities concerned to take immediate action without waiting for an official inquiry.—Sir KINGSLEY WOOD replied: My right hon. friend is aware of this case. He has no confirmation of cases of illness or of poisoning of stock from pollution. My right hon. friend has, however, received from the Rural District Council an application for consent to take proceedings against the company, and has directed a public inquiry to be held at the earliest practicable date into the application. He is afraid that an inquiry must first be held.

Poisoning Caused by Lemonade.

Mr. WILLIAM THORNE asked the Minister of Health if his attention had been called to a report by the Newcastle city analyst about the illness of at least 50 of the staff of one of the big shops in the city caused by antimony compounds contained in the lemonade which the assistants drank; if he was aware that the cause of the illness was in consequence of the enamel on the buckets which contained the made-up lemonade; and if he could state whether he intended taking any action in the matter.—Sir KINGSLEY WOOD replied: My right hon. friend's attention has been drawn to this case and he understands that the facts are as stated in the question. The city medical officer of health is preparing a report on the occurrence and on receipt of that report my right hon. friend will consider what action, if any, can be taken.

Medical News.

UNIVERSITY OF LONDON.—At recent examinations the following candidates were successful:—

M.D. EXAMINATION.

Branch I., Medicine.—Margery G. Blackie, London (R.F.H.) Sch. of Med. for Women; Frank R. Fletcher, London Hosp.; Francis H. K. Green, St. Bart.'s Hosp.; Bertram H. Jones, St. Thomas's Hosp.; John W. Joule and Robert A. E. Klaber, St. Bart.'s Hosp.; Geoffrey L. S. Kohnstam, King's Coll. Hosp.; Patrick H. O'Donovan, London Hosp.; Navroji Kharshedji Sabiar, Grant Med. Coll., Bombay, and Univ. Coll. Hosp.; and Ian H. Stevens, Univ. Coll. Hosp.

Branch II., Pathology.—Cicely Weatherall, London (R.F.H.) Sch. of Med. for Women.

Branch III., Psychological Medicine.—Norman Moulson, St. Bart.'s Hosp.

Branch IV., Midwifery and Diseases of Women—John J. R. Robinson, St. Thomas's Hosp.; Stephen J. Scurlock, London Hosp.; and Arthur J. Wrigley (University Medal), St. Thomas's Hosp.

Branch V., State Medicine.—William G. Booth, Guy's Hosp.

Branch VI., Tropical Medicine.—Percy C. C. Garnham (University Medal), St. Bart.'s Hosp.

M.S. EXAMINATION.

Branch I., Surgery.—Geraldine M. Barry, London (R.F.H.) Sch. of Med. for Women; Harold C. Edwards, King's Coll. Hosp.; and Gerald H. Steele, Univ. Coll. Hosp.

DIPLOMA IN BACTERIOLOGY.

Mohamed Abd El-Hamid Gohar, Kumarapuram Vythilinga Krishnan, Ram Bihari Lal, Marion Watson, and James A. Young.

B.SC. EXAMINATION.

Physiology.—Agnes Shore (first-class honours), Univ. Coll.; and Effie Slater (second-class honours), Univ. of Leeds.

At a meeting of the Senate on July 18th an offer was accepted from H.R.H. the Duke of Connaught to transfer to the University the Duchess of Connaught Memorial Hostel, and a committee was appointed to manage it as a hall of residence for students of European origin, preference, if necessary, being given to men from Canada and the other Dominions.

Mr. Robert Donaldson, M.D., Ch.B. Edin., F.R.C.S.E., D.P.H., was appointed as from August 1st, 1928, to the Sir William Dunn Chair of Pathology tenable at Guy's Hospital Medical School. Dr. Donaldson was demonstrator in pathology, University of Sheffield, 1909-11; senior demonstrator and lecturer, Bristol University, 1911-12; pathologist to the Royal Berks Hospital, Reading, 1912-20; and since January, 1920, has been pathologist to St. George's Hospital, and lecturer in pathology in the medical school there. He is also pathologist to St. Mary Abbot's Hospital.

the Princess Louise Hospital for Children, and the Hospital of St. John and St. Elizabeth.

Mr. S. J. Cowell, M.B., B.Ch. Camb., M.R.C.P., M.R.C.S., was appointed as from Sept. 1st, 1928, to the University Chair of Dietetics tenable at St. Thomas's Hospital Medical School. Dr. Cowell was appointed in December, 1920, junior assistant to the medical unit at University College Hospital, and since January, 1923, has been assistant to Prof. E. Mellanby at the University and Royal Infirmary, Sheffield. His recent work includes papers on the effect of iodine on hyperthyroidism in man and the action of irradiated ergosterol in human rickets.

Mr. H. D. Wright, M.D., Ch.B., D.Sc. Edin., B.A. Tasmania, M.R.C.P.E., was appointed as from Oct. 1st, 1928, to the University Readership in Bacteriology tenable at University College Hospital Medical School. Dr. Wright obtained the M.D. degree and gold medal at the University of Edinburgh in 1925, and the D.Sc. degree in 1927. He was Lister Research Fellow of the R.C.P., Edinburgh, in 1922. From 1920–23 he was lecturer in bacteriology in Edinburgh University, and from 1921–23 assistant director of the Research Laboratory of the Royal College of Physicians, Edinburgh. Since 1923 he has been lecturer in bacteriology at University College Hospital Medical School. He is assistant editor of the *Journal of Pathology and Bacteriology*.

Mr. S. L. Baker, M.R.C.S., D.P.H., was appointed as from Sept. 1st, 1928, to the University Readership in Morbid Anatomy and Histology tenable at Middlesex Hospital Medical School. Mr. Baker has held the posts of pathologist to the King Edward VII Sanatorium, Midhurst, 1919–22; senior assistant in the Bland-Sutton Institute of Pathology since July, 1922, and lecturer in morbid histology at the Middlesex Hospital Medical School since May, 1923.

The title of Professor of Morbid Anatomy in the University was conferred on Dr. G. W. de P. Nicholson in respect of the part-time post held by him at Guy's Hospital Medical School.

The title of Professor of Bacteriology in the University was conferred on Dr. Alexander Fleming in respect of the part-time post held by him at St. Mary's Hospital Medical School.

In view of Mr. S. A. Courtauld's munificent gifts for the Institute of Biochemistry and the Medical School of the Middlesex Hospital, it was resolved that the title of the University Chair of Biochemistry tenable at that Medical School should be changed to "Courtauld Chair of Biochemistry in the University of London."

King's College of Household and Social Science was admitted as a school of the University in the Faculty of Science (Household and Social Science only).

Sir Holburt Waring was appointed representative at the Seventh Centenary Celebrations of the University of Toulouse to be held in June, 1929. He has also been elected chairman of the Finance Committee.

Dr. John Fawcett has been elected chairman of the Committee of the Medical Members of the Senate.

Dr. E. Graham Little, M.P., has been re-elected chairman of the Council for External Students.

UNIVERSITY OF MANCHESTER.—The following post-graduate courses have been arranged for 1928–29. They will be mainly clinical in character. A whole-time intensive course in medicine and surgery will be held from Sept. 10th to 29th [illegible] y from Sept. 29th to Oct. [illegible] course will reside at St. [illegible], Manchester. A part-time course in diseases of the eye will be held from Oct. 2nd to Nov. 8th. In the spring of 1929 part-time courses on the application of radiology to medicine in diagnosis and treatment, on diseases of the skin, and on clinical pathology will be given. Clinical assistantships are offered in the medical, surgical, and special departments of the Manchester Royal Infirmary, Ancoats Hospital, and certain special hospitals. Further information, tariff, and syllabus can be obtained from the Dean of the Medical School.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The first woman to be elected Fellow of the College was introduced at the quarterly meeting of the College held on July 17th, when Dr. A. Justina Wilson, London, took her seat. The President, Dr. Robert A. Fleming, was in the chair.—Dr. G. D. T. Kerr Cross (Natal), Dr. R. H. H. Newton (Edinburgh), Dr. Thomas Ferguson (Darlington), Dr. B. H. H. Neven-Spence, and Dr. R. D. Mackenzie (Edinburgh) were elected Fellows of the College.—Dr. Robert Dods Brown has been appointed Morison lecturer for 1929.—It has been decided to confer the honorary Membership of the College upon Dr. John Stewart Muir, of Selkirk.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College, held on July 19th, the following candidates, having passed the requisite examinations, were admitted Fellows:—

William F. Angus, George I. Boyd, Harold C. Carter, Harman Singh Chhachhi, Ronald O. Davidson, Nevile J. Everard, Edgar S. Freshman, Fred C. Hunt, Stewart Hunter, Clifford S. James, Edward N. Jamieson, Robert O. Jones, James Kemyee, Kedar Nath Kulahreshiba, Arthur Leigh, Bantwal Canapathy Hallya, Willard G. Maclean, Ian H. MacGillivray, Cyril M. Plumptre, George E. J. A. Robinson, Isidore Rosin, Arthur J. Stout, Robert Strang, William R C. Stowe, Beatrice E. Turner and Robert Watson.

The Ivison Macadam Memorial Prize, consisting of bronze medal and set of books, was, after a competitive examination in organic chemistry, awarded to Mr. Maurice Goldfar.

ROCKEFELLER MEDICAL FELLOWSHIPS. — The Medical Research Council announce that on behalf of the Rockefeller Foundation they have made the following awards of Fellowships provided by the Foundation and tenable in the United States of America during the academic year 1928–29. These Fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine or surgery, and who are likely to profit by a period of work at a university or other chosen centre in America before taking up positions for higher teaching or research in the British Isles:—

Leonard Ernest Bayliss, B.A., Ph.D. Camb., Sharpey scholar at University College, London.

Albert Victor Neale, M.D. Birm., M.R.C.P. Lond., resident medical officer, Children's Hospital, Birmingham.

Francis John Worsley Roughton, M.A., Ph.D. Camb., lecturer in physico-chemical aspects of physiology, University of Cambridge (appointed on special conditions while retaining emoluments from other sources.)

Dorothy Stuart Russell, M.B., B.S. Lond., research worker in the Baron Institute of Pathology, London Hospital.

Arthur Wormall, M.Sc. Leeds, lecturer in biochemistry, University of Leeds.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—In the examinations of the Division of Tropical Medicine and Hygiene, at the end of this term, March–July, the following students passed with distinction:—

C. N. Griffin (winner of Duncan medal), M. C. Cairney, G. L. Chadha, C. D. Newman, and A. N. Sharma.

INTERNATIONAL MEDICAL POST-GRADUATE COURSES IN BERLIN.—The medical faculty of the University of Berlin, with the coöperation of the Lecturer's Association for Medical Continuation Courses and the Kaiserin Friedrich-Haus, which is an institution concerned with the post-graduate education of doctors, have arranged special courses for October, 1928. These will include a general course on pulmonary diseases, Oct. 1st–13th; a special course for nose, throat and ear specialists, Oct. 20th; and a course on pædiatrics, Oct. 15th–27th. A course on new methods in diagnosis and therapeutics with practical work in the wards and laboratories of the City Hospital, Friedrichshain, will also be held. Besides this special programme for October, short courses of two to four weeks and posts as guest-assistant in clinics, hospitals, and laboratories are available by arrangement. The courses are held in German, but many professors are able to lecture in other languages. Further information as to suitable lodgings, costs, and visits to clinics are obtainable from the Kaiserin Friedrich-Haus, 2–4, Luisenplatz, Berlin, NW 6.

THE SUPPLY OF MILK TO MOTHERS AND CHILDREN. The Minister of Health received, on July 24th, a deputation from the representatives of 12 metropolitan borough councils regarding the supply of milk for expectant and nursing mothers and children. The deputation was introduced by Mr. Thurtle, M.P., and Councillor Key, of Poplar, and Councillor Green, of Deptford, also spoke. They urged the reconsideration of letters recently issued by the Minister of Health which announced a reduction in the Exchequer grant for the supply of milk by maternity and child welfare authorities during the present financial year. The Minister said, in reply, that the reduction complained of had been made in view of the general need for economy. The only other way in which the necessary saving could be effected was to stop for the time being any further development of maternity and child welfare services, and it seemed preferable instead to make some reduction in the grants paid for the supply of milk. He was not insisting that local authorities should reduce their expenditure on milk, but had only intimated to them the maximum expenditure for this purpose which he could recognise for grant during the present year.

WELSH NATIONAL MEDICAL SCHOOL.—At a meeting held on July 24th at Bangor the Court of Governors of the University of Wales adopted the Draft Charter establishing the Welsh National Medical School as an independent school of the University. The Draft Charter will now be submitted to the Privy Council. Unfortunately the differences between the staff of the Cardiff Royal Infirmary and the authorities of the school have *not yet been resolved*. The Registrar of the University College of South Wales and Monmouthshire, of which College the school is still a constituent part, has informed present and prospective medical students that, until more complete arrangements have been made between the Hospital and the College authorities, students preparing for degrees and diplomas other than those given by the University of Wales cannot be accepted for courses of instruction in the final subjects.

PAYING PATIENTS AT RUGBY.—Five paying beds, two each for men and women, and one for children, are to be provided at St. Cross Hospital, Rugby. Subscribers with incomes between £300 and £700 a year, and their dependants, will pay £3 3*s.* per week for medical and surgical cases, and £4 4*s.* for complicated maternity cases. These fees will include attendance, ordinary hospital board, R.M.O.'s services, ordinary nursing, ordinary medicines, and ordinary surgical attendance. Non-subscribers will pay £2 2*s.* per week more under each heading. Minor operation fees will range from £3 3*s.* to £6 6*s.*, and major operation fees from £10 10*s.* to £15 15*s.*; the physicians' attendance fee will be a minimum of £3 3*s.*, with £1 1*s.* for each subsequent week.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A special course in diseases of the chest will be held at the Brompton Hospital for one week beginning July 30th (fee, £3 3*s.*). From August 6th to Sept. 1st clinical and cystoscopic demonstrations will be undertaken by the staff at All Saints Hospital, on Mondays, Wednesdays, Thursdays, and Saturdays (fee, £2 12*s.* 6*d.*). *Entrants should apply to the hospital for particulars of* times. For those interested in infants diseases there will be a two weeks' course under Dr. Eric Pritchard's direction at the Infants Hospital from August 13th to 25th (fee £3 3*s.*). Visits will be paid to baby welfare clinics such as that at Thavies Inn, to the Blind Babies' Home, Chorley Wood, &c. The Queen Mary's Hospital staff will undertake an all-day "refresher" course from August 27th to Sept. 8th, consisting of demonstrations in all departments of medicine, surgery, and the specialties, designed especially for panel practitioners (fee, £3 3*s.*). There is also a general course arranged continuously throughout the year for which tickets are issued for periods varying from one week to 12 months. Information, syllabuses, tickets, and copies of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

THE ROYAL VICTORIA EYE AND EAR HOSPITAL, DUBLIN.—Last week the Governor-General opened the new wing of this hospital. The wing supplies accommodation for 40 additional patients, besides improving the accommodation for the staff. The funds were provided by the estate of the late Mrs. Harvey Lewis, who left a considerable sum of money to build a hospital in Dublin. As the sum was insufficient for this purpose the executors sought the direction of the Courts, and after hearing many suggestions Mr. Justice Meredith assigned the bequest to the Royal Victoria Eye and Ear Hospital for the extension. The hospital is now probably one of the largest and best equipped in the British Isles. Last year 2017 intern patients were admitted, and 13,863 were attended in the extern department.

STREET NOISES.—At a joint council meeting of the People's League of Health, held at 12, Stratford-place, London, on July 12th, a resolution was passed :—

> That in view of the fact that *eminent neurologists* and mental experts have emphasised the grave effect on the nervous system of noises which tend to increase the incidence of functional mental and nervous disorders in our midst, this meeting urges upon the People's League of Health the desirability of calling the attention of the Government to the need for the control and diminution of preventable noises in our streets, and asks that the subject shall receive the serious attention of the Ministry of Health.

A letter embodying this request has been forwarded to *the* Minister of Health, who has been asked to receive a *deputation consisting* of Sir Farquhar Buzzard, Sir Maurice Craig, Sir Robert Armstrong-Jones, Sir James Purves-Stewart, Dr. A. F. Tredgold, Prof. G. Robertson, and Dr. Thomas Beaton.

METROPOLITAN HOSPITAL SUNDAY FUND.—At a meeting of the Council of this Fund, which was held at the Mansion House on July *20th, it* was announced that the year's total collection amounted to £81,500. Of this sum £81,300 will be distributed among hospitals, institutions, dispensaries, and nursing associations of the metropolis. The collections in the churches and chapels this year were *£2000 in* excess of last year.

THE MERSEYSIDE HOSPITALS COUNCIL.—This is the name now adopted by the Hospitals Council of the Liverpool Penny-in-the-Pound Scheme—which has been revised and renamed. The body consists of the officers and life members, nominees of the voluntary medical institutions, the honorary medical staffs of the associated hospitals, representatives of organised labour, the employers' associations, the contributors, the local municipality and Boards of Guardians, the University of Liverpool, the British Medical Association, and the Health Insurance Committee. The income limit for manual workers has been abolished, but non-manual contributors, whose income exceeds the following limits, will *be unable to secure free vouchers for service at the associated* hospitals: single persons, £4 per week; married persons without families, £5 per week; married persons with families, £6 per week. Ministers of any place of worship contributing on Hospital Sunday will be entitled to recommend for a free letter of introduction to an associated hospital any member of their congregation who has not been in a financial position to contribute to the Penny-in-the-Pound fund. Full contributors' privileges will be extended to all genuinely unable to obtain work, and free letters of introduction will be issued to all cases so certified by the appropriate trade-union.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, July 30th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY, August 1st.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE. Hammersmith, W.

MONDAY, July 30th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Simmonds: Surgical Out-patients.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Addison: Operations. 2 P.M., Dr. Shaw: Medical Out-patients.

WEDNESDAY, August 1st.—10 A.M., Dr. Owen: Medical Diseases of Children. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Gibb: Eye Department.

THURSDAY.—10 A.M., Dr. Granger Stewart: Neurological *Department.* 2 P.M., Mr. Donald Armour: Operations. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Ironside: Clinical Demonstration. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9 A.M., Mr. Vlasto: Throat, Nose and Ear Operations. 10 A.M., Dr. *Owen: Medical Diseases* of Children.

Daily 10 A.M. to 5 P.M., Saturdays 10 A.M. to 1 P.M., Medical, Surgical, and Special Departments. Operations, Anæsthetic Course, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W. 1.

MONDAY, July 30th, to SATURDAY, August 4th.—HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton), Fulham-road, S.W. Special Course for one week. Fee £3 3s. Syllabus sent on request, as also those for Special Courses arranged *for* August to December inclusive.

Appointments.

COWELL, S. J., M.B., Ch.B. Camb., has been appointed to the *newly instituted* Chair of Dietetics, University of London.

GARLAND, H. G., M.B., Ch.B. Leeds, Demonstrator in Pathology and Bacteriology at the University of Leeds.

ROY, D. W., M.B., B.Ch. Cantab., F.R.C.S. Eng., Honorary Obstetric Surgeon to St. George's Hospital.

Westminster Hospital: MEACOCK, M. J., L.R.C.P. Lond., M.R.C.S., and SWABY, E. E., L.R.C.P. Lond., M.R.C.S., Resident House Surgeons. HOWELLS, J. M., L.R.C.P. Lond., M.R.C.S.; KENDALL, A. W., M.B., B.S., M.R.C.S. Lond., L.R.C.P., Resident House Physicians.

Certifying Surgeons under the Factory and Workshop Acts: CAMPBELL, A. M., M.B., Ch.B. Glasg. (Islay, Argyll); CAMPBELL, T. H., M.B., Ch.B. Glasg. (Wishaw, Lanark); MACKAY, R., M.B., Ch.B. Aberd. (Beauly, Inverness); and THOMAS, G. L., M.B., Ch.B. Glasg. (St. Margaret's Hope, Orkney).

Vacancies.

For further information refer to the advertisement columns.

Bangor, Carnarvonshire and Anglesey Infirmary.—H.S. £200.

Birmingham, Birmingham and Midland Ear and Throat Hospital. 2nd H.S. At rate of £150.

Birmingham, Queen's Hospital.—Dental H.S. At rate of £50. Also Res. Anæsthetist. £70.

Blackburn County Borough.—Asst. Dentist. £475.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Bootle, Bootle Borough Hospital, Derby-road.—Sen. M.O. Also 2 Jun. M.O.'s. Each at rate of £150 and £125 respectively.

Bradford, Bradford Royal Infirmary.—Two H.S.'s. £150.

Brighton, Royal Sussex County Hospital.—H.S. £150.

Cambridge, Addenbrooke's Hospital.—H.P. At rate of £130.

Cardiff, Cardiff Royal Infirmary.—Three H.S.'s, three H.P.'s, and H.S. Gynæcological. Each at rate of £50. Also H.S. Ophthalmic. At rate of £75.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. H.S. £100.

Chester County Mental Hospital.—Fourth Asst. M.O. £350.

City of London Hospital for Diseases of the Heart, &c., Victoria Park, E.—H. P. At rate of £100.

Coventry, Coventry and Warwickshire Hospital.—Res. H.P. £125.

Delhi, Lady Hardinge Medical College.—Woman Professor of Physiology. Rs.500 a month.

Exeter, Royal Devon and Exeter Hospital.—H.S. At rate of £130.

Hertford, Hertford County Hospital.—H.P. At rate of £150.

Liverpoo' [illegible] Chair of Pathology. £1200.

London [illegible] *le End, E.*—Assistantship in t [illegible] £400.

Manchester, Baguley Sanatorium.—Asst. M.O. £350.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Jun. Res. M.O. £100.

Newcastle-upon-Tyne, Wooley Sanatorium, near Hexham.—Asst. M.O. £350.

Newcastle-upon-Tyne, Hospital for Sick Children.—Hon. P. to Skin Dept.

Northampton, County Borough.—Asst. M.O. £600.

Richmond, Surrey, Royal Hospital.—Hon. Asst. Radiologist. Also Jun. H.S. £100.

Rotherham, Rotherham Hospital.—H.P. £180.

St. George's Hospital, Hyde Park Corner, S.W.—Pathologist and Lecturer in Pathology.

Scarborough, Scarborough Hospital and Dispensary.—Two H.S.'s. Each at rate of £126.

Society of Apothecaries of London.—Examiner in Midwifery.

Taunton, Taunton and Somerset Hospital.—Sen. House M.O. £150.

Wakefield, Clayton Hospital.—H.S. At rate of £150.

Wallasey, Victoria Central Hospital.—Jun. H.S. At rate of £100.

The Chief Inspector of Factories announces the following vacancies for Certifying Factory Surgeons: Melbourne (Derbyshire) and Poole (Dorsetshire).

Births, Marriages, and Deaths.

BIRTHS.

BALL.—On July 14th, at Crooms Hill, Greenwich, the wife of Dr. Norman D. Ball, of a daughter.

PENHALE.—On July 10th, at Moor House, West Bromwich, the wife of Dr. W. P. Pênhale, of a daughter.

DEATHS.

DURHAM.—On July 16th, Frederic Durham, M.B., F.R.C.S., aged 87.

HEYWOOD SMITH.—On July 21st, at Chichester, Heywood Smith, M.A., M.D. Oxon., aged 90 years.

MOLYNEUX.—On July 16th, after a short illness, Echlin Storry Molyneux, M.R.C.S., L.R.C.P., of Siddington, Leamington Spa.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. I., 1928.

THE Index and Title-page to Vol. I., 1928, which was completed with the issue of June 30th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

RHEUMATIC DISEASES:

THE TREATMENT OF UNDERLYING INFECTION, INCLUDING VACCINES, THEIR USE AND ABUSE.*

BY SIR WILLIAM WILLCOX, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P. LOND.,

PHYSICIAN TO ST. MARY'S HOSPITAL, W.; MEDICAL ADVISER TO THE HOME OFFICE.

THE rheumatic diseases under consideration comprise: (1) acute and subacute rheumatism—the so-called "rheumatic fever"; (2) infective rheumatism, which includes:—

(*a*) Acute infective arthritis.

(*b*) Non-articular manifestations of chronic rheumatism in which the fibrous tissues are involved, such as fasciæ, aponeuroses, tendons, ligaments, bursæ, perineural tissues, bones, and periosteum (Heberden's nodes), fibrous deposits or thickenings of connective tissue (finger-pads, &c.). The comprehensive term "*fibrositis*" may be regarded as including all of these manifestations.

(*c*) "*Chronic arthritis*," or all forms of chronic rheumatism in which chronic joint changes occur, such as osteoarthritis, arthritis deformans, rheumatoid arthritis, chronic villous arthritis, &c. Forms of arthritis and fibrositis due to specific infections such as gonorrhœa, dysentery, tuberculosis, syphilis, &c., are excluded from consideration.

It will be universally admitted that an underlying infection is a most important ætiological factor in the causation of the rheumatic diseases under consideration. In most cases it is the primary causative factor.

Other ætiological factors play a part in the causation of rheumatic disease, such as defective hygienic conditions, an inadequate and improperly balanced dietary, hereditary diathesis, and so on. These may act by reducing the body resistance to infection, and they may predispose to the establishment of the underlying infection in the body.

The joint and connective tissue disorders which characterise rheumatic disease, whether it be rheumatic fever or one of the forms of chronic rheumatism, are not diseases per se, but are the local manifestations of the toxæmia of an underlying infection.

The proof of this statement is to be found in the other coexistent evidences of disease which accompany the rheumatic symptoms. Thus, in acute and subacute rheumatism, as was pointed out by the late Dr. W. B. Cheadle, the late Dr. David Lees, and Sir Thomas Barlow over 30 years ago, the joint symptoms are the least important part of the disease. Much graver manifestations of the disease were the heart complications such as pericarditis, myocarditis, endocarditis, the lung complications such as pleurisy and pneumonia, and the nervous complications such as chorea.

In chronic rheumatism, if carefully looked for, one always finds other evidence of the toxæmia besides the purely rheumatic symptoms, thus, a secondary anæmia is almost always present, and is accompanied by a general impairment of health, gastro-intestinal disorders, and other evidences of a toxæmia affecting different parts of the body.

(1) *Acute and Subacute Rheumatism.*

In childhood and pre-adult life the channel of the underlying infection appears to be the nasopharyngeal tract. Unhealthy tonsils are commonly found in the first attacks, and much evidence has been accumulated in recent years to prove the important part which infected tonsils play in the causation of acute and subacute rheumatism.

It has been my experience of hospital practice that one does not meet, to anything like the same extent to-day, with the virulent cases of rheumatic fever in children which were so common 30 years ago. Rheumatic hyperpyrexia rarely occurs at the present time, and the very severe cases of rheumatic fever in children are, I believe, much less common than formerly.

In my opinion, this improvement is largely due to the development of school hygiene and the medical supervision of children attending the elementary schools, whereby unhealthy conditions of the nasopharynx are recognised and receive, where necessary, appropriate medical and surgical treatment.

The improved sanitary conditions of houses, drainage, &c., and the care taken in refuse removal and disposal have also no doubt, played a part in reducing exposure to infection.

In acute and subacute rheumatism occurring in children during the pyrexial period, no special treatment is indicated for the underlying infection beyond the local treatment for existing nasopharyngeal conditions, and the usual treatment with salicylates.

---

* A paper read at the Bath Conference on Rheumatic Diseases.

When the acute condition has subsided, and, provided that no cardiac or other complications contra-indicate, it is most important that any diseased condition of the nasopharynx should receive appropriate treatment. Thus unhealthy tonsils and adenoid tissue should be removed, and any disease of the accessory nasal sinuses should receive attention. The stumps of tonsils that have been imperfectly removed are often foci of infection, and may be responsible for recurring rheumatic attacks. These, if present, should receive careful examination, and be removed if found unhealthy.

When any gross focus of infection has undergone removal as far as possible, no further special treatment of the underlying infection is necessary if the patient remains in good health.

It must be remembered that other foci of infection exist in the nasopharynx besides the tonsils and accessory nasal sinuses, thus the whole of this surface area contains tubular glands which secrete mucus as one of their functions, and the submucous region contains numerous collections of lymphoid tissue.

The recurrence of acute and subacute rheumatism in children in whom the tonsils and adenoids have been efficiently removed is due, I believe, to a persisting infection in these glands and lymphoid collections. Surgical treatment is impossible in such cases, and vaccine treatment may be of value, in addition to local treatment by sprays, vapours, and gargles, &c.

Should rheumatic symptoms still recur in cases in which unhealthy tonsils and adenoids are not present, it is advisable for a swab of the nasopharyngeal area to be taken and bacteriologically examined. If a definite infection with a pathogenic streptococcus is found, vaccine treatment is often of value.

It must be remembered that streptococci of nasopharyngeal origin are often very toxic in character. It is, therefore, advisable to give only small doses of an autogenous vaccine of this type. A weak vaccine such as 2,000,000 per c.cm. may be prepared, and a graduated course of inoculations given in doses of 2, 3, 4, 5 minims at intervals of five days, and then weekly doses, the dose being increased by 1 minim weekly for three months.

It has been my experience that much better results are gained by the use of autogenous vaccines than with stock vaccine prepared from other cases.

In acute and subacute rheumatism *affecting adults*, often other foci of infection than the nasopharynx play a part.

Secondary infections of the intestinal tract are commonly present, and also the dental region is liable to infection.

In such cases a careful examination should be made for secondary foci of infection in other regions than the nasopharynx, and these should receive appropriate treatment.

Thus, infected teeth should be removed at such time as this can be safely effected. Intestinal infections may be treated advantageously by Plombières douches, colon irrigations, &c.

Bacteriological examination of the urine, &c., should be made, and any existing infection of the urogenital tract receive suitable treatment.

In the acute stage of rheumatic fever, whether in children or adults, vaccine treatment in my experience should be entirely avoided.

The use of salicylates in full doses, combined with appropriate alkali-producing drugs, is the safest and best remedy in this stage. Often where response to treatment is not immediate, an increase in the dosage of sodium salicylate brings about a cessation of the acute symptoms. In this procedure care is taken that symptoms of acidosis are not present, and that acetone and diacetic acid are absent from the urine.

In exceptional cases of true acute rheumatism in adults, where response to salicylate treatment is tardy, antistreptococcus serum of appropriate type may be given. It is wise that the initial dose should be quite small—e.g., 5 c.cm. subcutaneously. If no unpleasant symptoms result from this, a dose of 20 c.cm. may be given in six hours, and this may be followed by two or three further doses of 20 c.cm. at intervals of 24 hours respectively. Any danger from anaphylactic shock is avoided by giving the preliminary small dose. Serum should never be given if there is any danger of anaphylaxis, and is, therefore, avoided where a patient has had, on previous occasions, animal serum administered subcutaneously.

After a course of antistreptococcic serum has been given, no further doses are permissible, since, after an interval of a few days there would be danger of anaphylactic shock should any doses be repeated.

In adults there may be a tendency for the recurrence of acute and subacute rheumatism in spite of the adequate treatment of gross foci of infection, and of other therapeutic measures, such as medicinal and spa treatment.

In such cases it is advisable to carry out bacteriological investigations of a nasopharyngeal swab, stools, and intestinal washings, and the urine (catheter specimen). Usually a pathogenic streptococcal infection is found.

A course of vaccine treatment with an autogenous vaccine made of the pathogenic streptococci from the various sources is sometimes beneficial.

It is advisable to use a vaccine of weak strength, such as 5,000,000 per c.cm. for a preliminary course, giving doses such as 2, 3, 4, 5 minims at intervals of five days respectively, and afterwards weekly inoculations, the dose being increased by 1 minim each week.

If this course gives good results a further course of inoculations with a stronger vaccine (50,000,000 per c.cm.) may be given in weekly doses of 2, 3, 4, 5, 6, 7, 8, 9, 10 minims respectively.

Contra-indications to vaccine treatment in adult cases would be the presence of any existing gross focus of infection which could be removed with advantage, such as septic tonsils or septic teeth, also any evidence of sensitisation such as the occurrence of gout, urticarial eruptions or prurigo, angioneurotic œdema, asthma, &c.

(2) *Infective Rheumatism.*

(*a*) *Acute Infective Arthritis.*—The great majority of cases of infective rheumatism are of the chronic type. Sometimes, however, acute cases occur in which there is evidence of an acute toxæmia, such as marked and continued pyrexia, and definite symptoms of acute arthritis or fibrositis.

Complete rest is the first essential.

A careful investigation should be made to discover the presence of any foci of infection. In cases of this type an active infection always exists, and the most judicial consideration is necessary before active measures are taken for dealing with any removable foci.

When infected teeth are the cause of acute toxæmia and infective arthritis, it is usually advisable and necessary to remove these in the acute stage of the illness.

One of many similar cases that have been under my care may be quoted :—

The patient, male, aged 57, seen May 26th, 1925, had suffered for six weeks from painful and tender swelling of the joints, both hands and wrists. The right knee was swollen and painful, fluid being present in the joint. The elbows and shoulders were painful. The temperature had ranged from 100° to 103° F. for the whole period. There was no history of rheumatic fever, and the condition did not respond in the least to salicylates.

An autogenous streptococcal vaccine, and antistreptococcal serum had been tried without benefit.

An X ray examination of the teeth showed the presence of periodontitis, but no apical infection was present. No other focus of infection was present. Sir Frank Colyer saw this patient in consultation with me, and was of opinion that an acute periodontitis was present.

Removal of the remaining 15 teeth was decided upon. The condition of the patient was so serious that a general anæsthetic was unsafe. The teeth were removed three at a time under local anæsthesia, an interval of 10 days being allowed between the respective extractions.

It was necessary for all the teeth to be removed, since not until then did the pyrexia completely subside and the swelling of the joints disappear. This patient has remained quite well since his illness, and the joints have been normal.

In conditions of acute toxæmia and infective arthritis due to septic tonsils, removal of the tonsils in the acute stage of illness is impossible owing to the grave risk that would be involved of local sepsis or of acute streptococcal septicæmia.

In such cases large doses of antistreptococcal serum are of value. They should be given with the precautions already described.

When the acute toxæmia has subsided and the temperature has remained normal for a few weeks, the removal of the tonsils will usually be advisable owing to the risk of development of chronic rheumatism.

A case of acute toxæmia and infective arthritis due to acute pharyngitis has recently been under my care in St. Mary's Hospital.

The patient, male, aged 28, was taken ill with pyrexia on Nov. 25th, 1927, acute pain and swelling of the joints of the hands, wrists, knees, and ankles occurred, there were pain and limitation of movement of the hip- and shoulder-joints. The pharynx was red and inflamed. The temperature ranged from 99° to 101° F. for five weeks.

There was no history of rheumatic fever, and the condition did not respond to large doses of salicylates.

X ray examination of the teeth showed nothing abnormal. My colleague, Mr. W. H. Dolamore, found the teeth healthy on clinical examination. The tonsils and accessory nasal sinuses were found free from sepsis by my colleague Mr. Cecil Graham.

There was no evidence of urogenital infection. Bacteriological examination of the stools and urine gave a normal result. A marked infection with *Streptococcus viridans* was found in the pharyngeal swab, and an autogenous vaccine of strength 5,000,000 per c.cm. was prepared. On Dec. 22nd, 23rd, and 24th doses of 20 c.cm. antistreptococcal serum were given. On Dec. 28th the temperature fell to normal. On Dec. 29th vaccine treatment was commenced, doses 1, 2, 3 minims being given at five-day intervals respectively, and afterwards weekly doses, the dose being increased by 1 minim each week.

On Jan. 14th the symptoms of pain and swelling of the joints had cleared up and the patient was discharged from hospital on Feb. 2nd, 1928, his joints and general condition being quite normal. The patient has resumed his work as chauffeur, and has been entirely free from any rheumatic symptoms.

"*Acute infective arthritis*" is really an acute toxæmia with acute arthritis as one of its manifestations. When recovery occurs from the acute toxæmia it is remarkable in many cases how completely the acute arthritis clears up, the joints becoming quite normal.

(*b*) *Chronic Rheumatism.*—In practically all cases of chronic fibrositis and chronic arthritis an underlying infection is present.

Careful search for the focus or foci of infection is the first step in treatment, and it is of the utmost importance that the relative significance of the various causal foci is appreciated when several are present. Sometimes the clinical symptoms are a guide. Thus, in cases of tonsillar and nasopharyngeal origin, there is a greater tendency for effusion into joints and tendon sheaths rather than for actual bony changes to occur. The joint symptoms may clear up to some extent and the improvement be followed by recurrences of the arthritis.

The tonsillar cases are more often seen in young people and are more likely to be associated with pyrexial periods.

Cases of intestinal origin are often associated with Heberden's nodes, and with bony changes and synovial proliferation—e.g., osteoarthritis and villous arthritis. The complexion is often sallow and a secondary anæmia is common. The colon is atonic and large, flatulent abdominal distension being present. The urine commonly contains a large excess of indican.

A careful clinical examination of the teeth, nasopharynx, gastro-intestinal tract, urogenital tract, should be supplemented by an X ray examination of the teeth and accessory nasal sinuses.

In some cases an X ray examination of the alimentary tract is advisable where diverticulitis, chronic appendicitis, cholecystitis, or intestinal stasis are suspected.

Bacteriological examination of the nasopharyngeal swab is of great value, since in the great majority of cases the causal organism is found in that region, often in almost pure culture. The teeth, tonsils, and antral discharges should be bacteriologically examined when operative measures have been carried out.

Bacteriological examination of the stools and also of the colon washings after an irrigation with normal saline are of value. In over 90 per cent. of cases of chronic arthritis under my care a streptococcus of the viridans group has been found in the stools. The streptococcal infection is, no doubt, in most cases secondary to a pre-existing dental or nasopharyngeal infection.

Search should be made for the non-lactose fermenting group of coliform organisms. These are known as the "parenteric group," and include *Bacillus asiaticus* and pseudo asiaticus, *Bacillus fæcalis alkaligenes* and pseudo fæcalis alkaligenes, bacillus of epidemic jaundice, bacillus morgan, the food poisoning group, such as *Bacillus aertrycke*, *Bacillus enteritidis* of Gaertner, &c.

I have found a parenteric intestinal infection associated with the streptococcal infection in an appreciable number of cases of chronic rheumatism, and I believe that this plays a part, perhaps a minor one, in the ætiology of these cases.

The combination of a streptococcus infection with a parenteric infection in the bowel may produce an enhanced pathological effect by symbiotic action. The close association and resemblance of the parenteric organisms with the bacillary dysentery group (which are well known to cause arthritis) is sufficient to call for careful attention.

Where a prostatic cause is suspected, prostatic massage is advisable before collecting a sample of urine for bacteriological examination.

Swabs from the vagina, cervix uteri, or uterus may require bacteriological examination if clinical symptoms suggest it.

In almost all cases of chronic rheumatism investigated in the bacteriological department of St. Mary's Hospital a streptococcus of the viridans group has been found, and this is sometimes accompanied by a hæmolytic streptococcus. The streptococcal organism must, I think, be regarded as the one usually responsible for the underlying infection.

The treatment of the underlying infection in chronic cases involves:—

1. Removal of gross foci of infection where this can be undertaken without risk or harm. Teeth showing periapical bone necrosis must be removed.

2. Where there is marked periodontal disease, or where dead teeth, or stumps, are present, or unerupted teeth, or dental cysts showing evidence of infection, careful consideration must be given to the question of radical surgical treatment.

3. When the rheumatic trouble is of a serious type, and where the evidence points to there being an important factor in causation, it is advisable for radical treatment to be carried out.

The proper procedure is, I think, to treat each case on its merits, and to arrive at a decision after considering all the points for and against surgical treatment. No hard-and-fast rules can be laid down for all cases.

The question of surgical treatment of unhealthy tonsils or tonsillar stumps must receive careful consideration. It should be carried out where the clinical type of the disease points to these as the causal factor. Where the rheumatic trouble is serious and persistent and no other important cause is found the indication for surgical treatment is strong and well founded.

Infected maxillary antra require adequate drainage by surgical measures, and infected accessory nasal sinuses may call for operative treatment.

Unhealthy conditions of the colon call for suitable treatment by means of special diet, Plombières douches, colon irrigations, or abdominal massage, &c.

The *underlying infection* can be further treated by measures taken which will raise the immunity of the body, thus *general measures* are of value such as suitable climatic conditions, artificial sunlight, a dietary which is well balanced and rich in nutritive vitamin-containing foods, the supplementing of endocrine deficiencies by administration of suitable doses of thyroid gland, &c.

Special Biological Measures.

Vaccine therapy.—Vaccines should not be given until the case has received the fullest clinical investigation, and any existing foci of infection received appropriate treatment.

An abuse of vaccine therapy is the administration of vaccines to cases of chronic rheumatism where obvious foci of infection are present—for example, septic teeth, septic tonsils, or infected antra. In such cases more harm than good must result.

Vaccines cannot raise the immunity where gross septic foci exist such as these, and they are likely to cause severe reactions and possibly complications such as urticarial eruptions, prurigo, &c.

Vaccines are contra-indicated where "sensitisation" to the toxins from the infection exists. Examples of this are recurring urticarial eruptions, prurigo, certain erythemata, gout, angioneurotic œdema.

In exophthalmic goitre, if associated with chronic rheumatism, vaccines may increase the symptoms of the thyroid disturbance and should be avoided. If nephritis is present, vaccines may cause an exacerbation of the renal symptoms and are dangerous.

If retinal vascular lesions of toxic origin are present in association with chronic rheumatism vaccine treatment is best avoided owing to the risk of further retinal damage.

Vaccines are of value in cases of chronic rheumatism where any gross focus of infection has been removed and where the toxic process is being carried on by the chronic infection of a mucous surface with its accompanying glandular tissue. Thus, in chronic intestinal or nasopharyngeal infections vaccine treatment may be used to supplement the other measures.

Complete bacteriological examination should be made of all the possible channels of infection and an autogenous vaccine prepared. This is usually one composed of streptococcal organism of the viridans group. The streptococci from different foci may with advantage be combined in suitable proportions.

For reasons already quoted it is advisable to commence with a vaccine of weak strength, say 5,000,000 per c.cm., and, after a preliminary course of this, to proceed with a stronger vaccine of, say, 50,000,000 per c.cm., giving carefully graduated doses. By this method of procedure unpleasant reactions are obviated, and the occurrence of harmful complications is guarded against.

Any evidence of symptoms of sensitisation are an indication for discontinuance of this line of treatment. In my experience effective immunisation is more readily obtained by carefully graduated doses of a weak vaccine than by giving the large doses advocated by some.

Where a parenteric intestinal infection exists in company with the streptococcal, and when a positive agglutination test is given by the patient's blood serum and the organism found, it is often advisable to give a short course of inoculations with the autogenous parenteric vaccine. This may be made of strength 50,000,000 per c.cm., and weekly doses of 2, 4, 6, 8, 10 minims given.

At the end of this course a further bacteriological examination of the stools should be made to determine if the infection still persists.

Stock streptococcal vaccines made from other patients are, in my experience, far inferior to autogenous vaccines, and are not recommended for use.

Antistreptococcal serum is not indicated in cases of chronic rheumatism.

Protein shock therapy, such as injection of peptone solution or of typhoid vaccine has, in my experience, been disappointing. In some cases, definite temporary improvement has occurred, but this has often been followed by a relapse into the former condition.

The Action of Vaccines in Chronic Rheumatism.

Properly graduated doses of an autogenous vaccine are of value in raising the immunity of the body to the causal toxæmia, and they, therefore, promote an improvement in the general condition of health.

The effect of an inoculation is to cause some local reaction in the affected joint. The increase in blood-supply consequent on this has a beneficial local effect. Vaccines are undoubtedly helpful in promoting absorption of inflammatory exudates. It cannot be claimed that they will effect improvement in the bony changes which have occurred in a damaged joint.

In some cases, such as old-standing osteoarthritis of the hip, vaccine treatment is undoubtedly of value in relieving pain and in checking the progress of the arthritis.

Vaccine treatment can with advantage be combined with other methods of treatment.

A BABIES CLUB.

AN infant welfare centre on a self-supporting basis has been opened at Stanley Cottage 35, Danvers-street, Paulton's-square, Chelsea. Dr. W. H. L. McCarthy, medical officer of health for Chelsea, is on the committee of management, and Dr. Harold Waller is medical officer to the centre. The object of this "Babies Club" is the instruction in the hygienic management of young children of mothers of the professional class who cannot afford repeatedly to call in a doctor for purposes of general supervision. Any mother wishing to bring her child to the club must first inform her family doctor of her intention and obtain his coöperation. Cases of illness discovered at the club will be referred back to him. Subscribers are not at liberty to ask the medical officer to attend their children in case of illness in their own homes; he can do so only at the request of their own doctor. Home visits by the nurse-superintendent are, however, covered by the subscription. The fee payable is five guineas per child for one year, or seven and a half guineas for two children in one family. The estimated expense of running the club is £750 per annum, and the estimated annual income, on the basis of one clinic a week and 150 members, is £787. There has been a steady increase in numbers since the club was opened in November last. The capital necessary to start the venture was provided from private loans, on which 5 per cent. income is to be paid if funds permit; it is hoped to repay the loans out of the funds of the club. £300 is still required for equipment and running expenses until the full complement of members is reached.

THE QUEEN'S NURSES IN IRELAND.

FOR some months past there has been anxiety among those interested in the admirable work of the Queen's nurses (better known as Jubilee nurses) in Ireland. Since the institution was founded about 40 years ago for the nursing of the sick poor in their own homes, the nurses in Ireland have been under the control of a Central Council meeting in Dublin, which was subordinate only to the Executive in London. All parts of Ireland have been represented on the Central Council, and no complaint has ever been made that partiality was shown toward one district rather than another. A few months ago, however, a sum of money raised in Northern Ireland to found a memorial to Queen Alexandra was offered to the Belfast Advisory Committee to extend the work of the nurses in Northern Ireland, on condition that a Council should be established for Northern Ireland entirely independent of the existing Council for Ireland. The proposal, warmly championed by Lady Londonderry, was opposed throughout the greater part of Ireland, and nowhere more determinedly than in some of the counties of Northern Ireland. After considerable controversy the proposal came before the Executive in London, which appointed a subcommittee, under the chairmanship of Sir William Hale-White, to inquire into the matter. The subcommittee took evidence in favour of and against the proposal, and has now reported against it. In the opinion of the subcommittee no one in the Irish Free State favoured the proposal, and many in Northern Ireland disliked it. The large majority of those interested in the work of the nurses in Ireland were definitely against shou[illegible]nge. Moreover, the size of Northern Ireland would In adultsr the unnecessary expense of a Council, with a [illegible] and suuaining establishment. The subcommittee has not justi[illegible] of groaggestions in the endeavour to meet specific offices and [illegible]ch as by Lady Londonderry and her friends, made certain s[illegible] criticisms made [illegible] hoping thereby to prevent any injury being done to the work of the nurses, which is universally appreciated. This will be the hope of many in Ireland who do not see why political divisions should be permitted to interfere with charitable activity.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the committee 37 applications for assistance were considered, and £520 16s. voted to 32 cases. As the holiday season approaches appeals come from widows and others asking for help towards the holiday expenses for children of medical men. An appeal is made to all who sympathise with the children's need during the summer holidays, to support this work of the Fund by sending subscriptions to the hon. treasurer, 11, Chandos-street, Cavendish-square, London, W. 1. The two following cases are quoted as an example:—

Mrs. X, whose husband, M.B. Lond., is now in a mental home as a free patient, has charge of three children. She has no income other than what she can make by needlework. The eldest child, a girl of 12, is educated by her godmother. The Fund pays the school fees for the son, age 9; the third child is at home. The applicant writes: "I had a breakdown in the middle of April and have been able to do so little work since that the seven weeks' summer holidays is rather a nightmare to me as regards finance." A grant of £7 10s. was voted.

M.R.C.S. who died in 1921, leaving five children, ages 12 to 4. One is at Epsom College, one at a girl's school, and three at orphanages. These children are dependent on relatives who are unable to contribute. Fund voted £15 for the children's holidays.

Other cases helped were:—

L.M.S.S.A. at the age of 70, who was in practice for 21 years, broke down in health in 1920. Ill health and ill luck followed each other. He is suffering from bronchitis and diabetes, and unable to work. He is entirely without means except the 15s. a week which his wife is able to make as a cook-housekeeper in some service flats. Voted £40.

L.R.C.P. & S., aged 72. The applicant is a widower, nearly blind with diabetes, and is confined to his bed. His income is the Old Age Pension £26 and Epsom Pension £40. Fund granted £25, making his total income £91; his rent for his room is £26.

L.R.C.P. & S. Edin., aged 68, whose wife is delicate, aged 66, had to give up his regular practice 24 years ago, since when he has worked as locum tenens. He has been handicapped by ill health, and during the last nine months has been unable to work and got into financial difficulties. Voted £40.

L.R.C.P. &. S., died in 1926 at the age of 39, leaving a widow and two infants ill provided for. The fund assisted the widow in 1927. In May, 1928, the widow died, leaving the two orphans, aged 8½ and 7½. Assistance was asked from the Fund. The case has been handed over to our Ladies' Guild to administer.

THE WELLCOME HISTORICAL MEDICAL MUSEUM.

THE souvenir programme issued in connexion with the visit paid by the African Society on July 11th to the Wellcome Historical Medical Museum takes the form of an attractive little book. This contains an illustrated catalogue, and an account of the inauguration ceremony in 1913, and of the speeches on Oct. 14th, 1926, when the reorganised and extended museum was reopened by Sir Humphry Rolleston. This is one of the permanent exhibitions in London that deserve a visit from doctors. The hall of primitive medicine and the alchemy room will appeal especially to those interested in ancient superstitions, while the development of pharmacy is neatly shown in the models of the chemist shops of different ages. Specimens, pictures, and statues are displayed in other rooms. The museum is at 54A, Wigmore-street, London, W.

A CONVENIENT HÆMOGLOBIN CHART.

WE have received from Messrs. Reed and Carnrick a handy hæmoglobin chart, which consists of a cardboard disc pinned by a paper clip to several layers of blotting-paper of larger diameter. These layers are separated from each other by grease-proof paper. The disc is divided into seven sectors of varying tints of red. If a drop of blood is placed on the filter paper, the chart may be rotated while the blood is still moist, until the colour is matched by one of the sectors which are numbered 10, 30, 50, 70, 80, 90, and 100, indicating the hæmoglobin percentage represented. When the first piece of blotting paper has been used it can be thrown away, and the next lower used when occasion demands. As a simple hæmoglobinometer this chart should be quite useful. It is unfortunate that the letterpress describing its mechanism claims rather too much. The suggestion is that the presence of mild, moderate, or severe anæmia can be determined merely by consulting the chart, whereas, of course, it is not so much the percentage of hæmoglobin, but the colour-index, which is the relation of hæmoglobin to the number of corpuscles in the blood to be tested, that gives a valuable indication of the type and degree of anæmia in any subject. There is no reason, however, why this hæmoglobinometer should not be as useful as more complex ones, provided it is not expected to take the place of a red cell count.

An Address

ON THE

PIDEMIOLOGY OF CHILDREN'S INFECTIOUS DISEASES.*

Y ULRICH FRIEDEMANN, M.D. BERLIN,
AORDINARY PROFESSOR AT THE UNIVERSITY OF BERLIN;
DIRECTOR OF THE INFECTIOUS DISEASES DEPARTMENT
OF THE RUDOLF VIRCHOW HOSPITAL.

. NOTABLE change has taken place during recent rs in the conception of epidemic diseases, a change ch is of importance not only from a theoretical also from a practical point of view. The classical ohylaxis of epidemic diseases has been established he basis of the doctrine of Robert Koch, that the aogenic microbes are *only* to be found in those ases which they have caused, while in healthy ple they are either absent or found only as an eption. A sharp line can be drawn between these aogenic microbes and the group of saprophytes, ch, lacking any specificity, are found on the skin in the mucous membranes of any person. The lern doctrine holds that between pathogenic robes and saprophytes there is only an artificial ntitative distinction. We know that in a con-rable number of diseases the causative microbes pathogenic only for a very limited number of aan beings, and are but inoffensive saprophytes the majority. Infection is therefore not identical a infectious disease, save in a very few cases. We e to differentiate between infection followed by ease and infection without disease. The latter can called "latent infection" and, in its propagation, tent epidemisation" ("latente Durchseuchung"). s easy to understand that the extent of "latent lemisation" is of the utmost importance for ventive measures. We must therefore get an ct idea of the extent of the latent epidemisation each infectious disease. In an extensive latent lemisation we may assume the following two ors: (1) a very small inborn susceptibility of ividuals to the contagious disease; (2) an extensive ead of the specific microbes. The first statement s not need any interpretation. If the microbe is virulent for man that infection coincides with the aptoms of disease, we experience a manifest, not tent epidemisation—for example, measles.

Latent Immunisation.

he spread of microbes depends upon the manner their excretion. The latter is of the greatest oortance in diseases conveyed through droplet ection, and in these latent epidemisation plays an oortant part. The practical importance of latent demisation lies not only in the prophylaxis of demics, but also in a phenomenon which I call tent immunisation." Latent infection, as well as overy from an infectious disease, may confer ting immunity. In a large population latent munisation must naturally be a function of age. e older an individual the more frequently he has en exposed to latent infection, and the higher erefore is his degree of latent immunisation.

We have known for a long time that the insuscepti-ity of adults to measles is due to the fact that almost eryone gets over them in youth. During the asles epidemic on the Faroë Isles, all the inhabitants, espective of age, were afflicted. Such an explana-n is impossible for acute poliomyelitis, diphtheria, d scarlet fever. Since the number of children who ntract these diseases is comparatively small, it is ficult to understand the immunity of adults. The planation is that latent epidemisation takes the ice of the disease. The immunity of adults towards ildren's infectious diseases is not inborn but is the result of latent epidemisation. The restriction of certain infectious diseases to the period of infancy is explained by the enormous extent of manifest or latent epidemisation in these diseases. Since this extent depends on the method of propagation of the microbes, it is not an accident that all infectious children's diseases are spread by means of droplet infection, whereas infectious intestinal diseases are not restricted exclusively to infancy. The relative resistance of adults towards the saprophytes of the mucous membranes of the upper respiratory tracts—the streptococci and pneumococci—is acquired by latent epidemisation. Among primitive races and people living far from civilisation very dangerous contagious diseases are caused by these organisms—e.g., pneumonia among the negroes in the mines of the Transvaal and the black workmen of the Panama Canal, and, during the war, among American soldiers recruited from country districts. The infant responds to an infection like an individual of *a primitive race.* The malignancy of measles in children under three does not depend upon the virus itself but upon the mixed infection with streptococci, which causes severe septic and contagious bronchial pneumonias. The course taken by children's infectious diseases is often dominated by these mixed infections. The numerous trifling infections which take place during childhood confer an immunity to pneumococci and streptococci, transforming them in the adult into inoffensive saprophytes.

We have at our disposal four methods for the study of infectious diseases: (1) bacteriological analysis; (2) immunity reactions, such as the Schick test in diphtheria and the Dick test in scarlatina; (3) the epidemiological method (statistics); (4) the methods of experimental epidemiology—the newest method taken by epidemiological science. This development we owe to the studies of Topley in England, and of Flexner, Amoss, and Webster in U.S.A.

ACUTE POLIOMYELITIS.

Acute poliomyelitis, which lately has attracted especial interest, shows the strongly marked characteristics of children's infectious diseases. In 1840 the German physician Heine was the first to outline the pathography of poliomyelitis as an *entity.* At that time only a few cases had been recorded, and nobody thought that the disease was contagious. In 1895 Medine referred to an epidemic in Sweden; there were only 43 cases. In 1905 a second epidemic of 1000 cases occurred in Sweden, and soon spread all over Norway, Germany, Austria, and America. Since that time poliomyelitis has never completely disappeared. It was not, however, until 1910 that it rose to a pandemic of considerable proportions, which lasted three years in Sweden and affected 10,000 persons. This outbreak was followed by the spread of the disease almost all over the world. In Germany we have noticed an increase in the number of cases, and it may be that we are on the eve of a new outbreak.

Poliomyelitis epidemics follow a very characteristic course. The spread of most contagious diseases is favoured by communication and has a direct connexion with the density of population. Poliomyelitis especially affects lonely and remote districts. The fact that the majority of cases are isolated and have no obvious connexion with other cases seemed to contradict the contagiousness of the disease, but during epidemics the contagiousness rises considerably. During the Swedish epidemic of 1910–1913, according to Wernstedt, 18·6 per cent. of the cases were group cases in one house, while 38 per cent. were caused by infection in hospitals. On account of these peculiarities poliomyelitis has been held for a long time to be infectious, but not contagious. Some authors supposed that the virus lived in the earth, and thus explained the spread of the disease in country districts. Others thought that it was propagated by insects. This opinion was supported by the seasonal incidence curve. While most children's diseases have their annual maximum in the autumn, poliomyelitis is a summer disease, at its maximum in July and

---

* Delivered in London at the invitation of the Health Organi-ion of the League of Nations at an International Course for dical Officers of Health.

August. But as in winter epidemics the number of cases is considerable, we must exclude an exclusive or prevailing participation of insects in the propagation of the disease. The opinion that poliomyelitis is a primary disease of domestic animals is without foundation.

It was a valuable advance when Wickmann laid all these doubts at rest and proved, by an exact cartographic study of the Swedish epidemic of 1905, the contagious character of the disease. The epidemic arose from isolated centres scattered all over the country, but the cases showed a pronounced group-formation round these first centres, from which they afterwards spread in a radiate form, following the trade routes. It was Wickmann who made the important observation that connexion between the single cases could often be traced through abortive cases without palsies.

Remaining contradictions were solved by Wernstedt's epidemiological studies during the Swedish epidemic of 1910–1913. When Wernstedt, following the example of Wickmann, made an exact cartographic note of the cases of this epidemic, he was surprised to discover that all the districts where cases of poliomyelitis had occurred in 1905 were free from infection during the epidemic of 1910. Sometimes these districts were quite surrounded by the epidemic, and were therefore proved to be immune. This immunity could only be due to the epidemic of 1905, but this fact is difficult to explain. Poliomyelitis, though it travels through countries at a rapid rate, affects few individuals in each country. For instance, the cases in the districts visited by the epidemic of 1905 numbered but 1 to 2 per cent. of the population; nevertheless, the whole population had become immune. The entire population must, therefore, have come in close contact with the microbe without being affected. This, then, is the first example of an extensive latent epidemisation. The hypothesis of latent epidemisation readily explains the other peculiarities of the epidemiology of poliomyelitis, including: (1) the dependence of the spread upon the density of population; (2) the incidence of the epidemic at different ages.

The more congested the population of a district and the more active its communication with its neighbours, the easier is the spread of the ubiquitous poliomyelitis virus in the intervals between epidemics, and the more readily will it latently infect and immunise the population. On the other hand, the population of remote districts is deprived of this preventive effect and is therefore much more exposed to infection. The frequency of group cases in a household will be the higher the greater the number of susceptible persons united under the same roof. Table I. demonstrates this:—

TABLE I.

Size of town.	Incidence-rate (per cent.).
More than 100,000 inhabitants	8·8
100,000 to 10,000 inhabitants	9·4
Country town, less than 10,000 inhabitants ..	13
Country	20·7

Poliomyelitis is generally considered to be essentially a disease of the earlier years of life, but its age-incidence depends also in a very characteristic manner upon conditions of local distribution and traffic. If the population is not dense and communications not developed, poliomyelitis ceases to be a children's disease and more adults are affected. This will be seen from Table II. and Fig. 1.

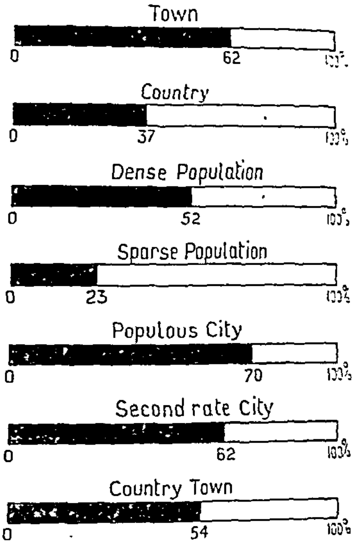
TABLE II.

Age-group.	Town.	Country districts.	Population.		Populous city.	Small town.	Country town.
			Dense.	Sparse.			
	%	%	%	%	%	%	%
Years 0–5	61·8	37·5	51·8	23·0	70	61·8	54·2
Over 6 ..	38·2	62·5	48·2	77·0	30	38·2	45·8

In districts where the poliomyelitis virus has little or no opportunity to spread, there is a high susceptibility among adults. The more the population is exposed to the virus, the more is the susceptibility restricted to the earliest years of life. Should this hypothesis prove to be correct, there should be no difference in susceptibility between young and old where poliomyelitis is imported into a population that has never been in contact with it before. A. Müller has reported an outbreak of poliomyelitis on a Pacific island, during which 37 per cent. of the natives were affected, and the maximum incidence was between the ages of 12 and 40.

I have restricted myself to the Swedish epidemics, because their epidemiological laws have been the most thoroughly studied. These significant results have been obtained from epidemiological statistics alone.

FIG. 1.



Age-incidence of poliomyelitis in different districts. The black rectangles represent the age-groups from 0–5 years, the white rectangles the ages over 6 years.

Ætiological Investigations.

To Landsteiner, Levaditi, Flexner, Wiesner, Römer, and others we owe the discovery that poliomyelitis may be transmitted to the lower monkeys by subdural inoculation of the brain and spinal cord of poliomyelitis cases. Flexner and Amoss were able to prove by experiments the highly important epidemiological fact that the virus is also to be found in the nasal secretion of the infected animals, and that infection could be induced by dropping the virus on the intact mucous membrane of the nose.. These results suggest that in man the mucous membrane of the nose is the most important portal of entry as well as the chief path of elimination of the virus, and we may further suppose that case-to-case infection takes place by droplet infection. This statement is in harmony with existing epidemiological conceptions. Kling and Wernstedt have demonstrated the poliomyelitis virus in the nasal secretion of man, but it is doubtful whether this is the only mode of virus transmission. Since in the beginning of poliomyelitis diarrhœas are not rare, it is plausible that the virus may be excreted in the fæces. Flexner and Amoss have found it in the excreta of monkeys, but droplet infection is in all probability the more important factor, because in this way the virus gains a far wider propagation. Spontaneous fluctuations of virulence observed in poliomyelitis virus by Flexner and Amoss are of great interest and may lead to an explanation of the coming and going of epidemics.

DIPHTHERIA.
